AUTUMN
BOOK

Peak quality in chromatography!

Pharmacia Columns are
designed to exploit to
the full the separation
properties of your
bed material.

- High resolution
- Ease of performance
  and maintenance
- Inertness
- Aqueous or solvent work
- Low or medium pressure
- Fast and easy sample application
- Reversed flow and recycling
- Compatible with a wide range
  of accessories for systems building
- Reliability

The quality of
your work deserves
the quality of
Pharmacia Columns.

Ask for our free Catalogue
and choose
from the wide range of
Pharmacia Columns.
There is one to
suit your application.

The purpose of the journal

The Need for a new journal

The last twenty years have seen major developments in science education and interest has been accelerating in the past few years. Current publications on science education are restricted to either teachers or researchers, to a single subject, to a single level or to a single country.
The European Journal of Science Education will bridge the gap between researchers, administrators and teachers, and between countries, and will deal with all levels of science teaching. Although its flavour will be European, an international advisory board will ensure that the needs of a world-wide readership will be met.

Languages

The journal will be published in English but with summaries of all principal items in French, German and Spanish.

Scope ~~R501~~ RP402

The journal will cover educational issues in general science, integrated science, biology, chemistry, physics, earth sciences, geology and technology. It will report research to teachers at primary, secondary and tertiary levels and will include science education in industry and commerce.
Each issue will have four main sections:

- Major articles – reviews and surveys of the main areas in science education.
- A section on innovation and development in science teaching.
- Research reports – results of original studies, with emphasis on applied and applicable research.
- News and Information about research projects, conferences, personal and institutional news, and readers' correspondence.

For further information please apply to the publisher. Sample copies are available on request.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,**1 (1975) and **264,** v, 11 Nov. (1976).

Nuclear Power and the Energy Crisis: Politics of the Atomic Industry (Duncan Burn) — *L. Rotherham* 143

Culturing cells?

Would you like a cell culture technique
which gives you higher cell yields for less effort,
less time and less money?

You should know more about microcarrier culture with

Cytodex™ 1

- High cell yields
- Much smaller working volumes
- Easy control and monitoring of cultures
- Simple harvesting of cells without centrifugation
- Saves you space, effort, time and money

One gram of Cytodex 1 gives you the same capacity for cell growth as 7 roller bottles or 76 standard Petri dishes.

Cytodex™ 1 – the new dimension in cell culture.

Ask for more information today, and prove it for yourself.

1976	£2.50	US $5.00
1977	£2.50	US $5.00

Listing the year's papers by both author and subject, they assist quick, easy reference to past issues.

BINDERS

Keep your copies of *Nature* protected in durable black PVC binders:

- 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- title blocked in gold on spine
- panel on spine for your own references

Each binder is designed to take two volumes of *Nature*; three binders will serve for a year.

Prices (including postage): UK £3.00 each, three for £8.00; Rest of World US $6.00, three for US $16.00.

To order, please send details and correct remittance to:

"I'll tell you some things about our Forma blood bank refrigerator that will make you think twice before you buy someone else's."

No doubt your blood bank is as busy as ours. We're in and out of this refrigerator at least thirty times a day. Restocking, taking inventory, testing alarm probes.

And when you think about it, those door openings can add up to a potentially dangerous temperature control loss that may jeopardize the safety of whole blood.

So when the Forma Sales Representative told us about Forma's fast +4°C temperature recovery after door openings, oversized refrigeration systems, thermally weighted probes, ringback alarm systems with remote alarm contacts, inkless recorders, and top-to-bottom temperature uniformity, we listened.

Then he showed us the performance test results for both their 300 bag and 588 bag capacity refrigerators. And those control, uniformity, and recovery numbers convinced us.

We bought the 300 bag capacity Model 3880. Later we ordered the optional drawer divider kit. And we're rapidly growing into a larger Model 3882 with its 588 bag capacity.

We think Forma's taken a realistic approach in the design of their blood bank equipment. Refrigerators, red cell and plasma freezers, and more. Because their primary concern is the safe storage of whole blood and blood products.

That's why they're called the Blood Bank People. And that's why we'll call them often.

nature

9 November 1978

Now reason can prevail

Sir Gordon Wolstenholme, Chairman of Britain's Genetic Manipulation Advisory Group, said on London Weekend Television last Sunday that GMAG's new system of guidelines for assessing the risks of genetic manipulation experiments "will be so full of sense in the end that it will be the one which will predominate." GMAG has not yet formally adopted the system (which is based on a version of numerical risk analysis) and has opened the subject for debate with the article below (p 104).

The revised guidelines proposed by the US National Institutes of Health are in many ways arbitrary. They are thus open to bitter public attack. The new GMAG system, on the other hand, is rational and therefore more defensible; and it is flexible in that experiments on risk are encouraged and new data can easily be incorporated. GMAG should be encouraged to adopt the new system. But GMAG's path is not strewn with roses.

First, there are internal problems. While the procedure outlined below is clearly rational, it still leaves many of the cards in GMAG's hands. 'Qualitative' biological judgements have to be made alongside the calculations, and it would help if GMAG were to be more explicit about these judgements. It would help also if GMAG's existing case law—which will still be applied where data is not available to support the more scientific system—were to be published.

It would also help if the history of the more numerical parts of the procedure were known. Sydney Brenner had the original idea of calculating a number of separable 'risk factors' for each experiment (last week he said: "I don't believe anything until I see numbers"). His idea was developed in the Safe Vectors Sub-Committee of GMAG, where a trial was run of numerical assessment. Individuals were given a list of experiments whose risks were to be calculated; but they came up with very different figures. However the *ranking* of the experiments with respect to risk was highly consistent, and hence the stress on the use of the figures for rank rather than as absolute numbers in the GMAG document. Also, there is no mention of a 'scale-up' factor in the report. The system is flexible enough that one could be included, but it is not the easy matter it might at first seem. As one GMAG member said "which would you be more afraid of: an experimenter dropping a one-litre glass flask, or an escape from a sealed stainless steel industrial plant containing 10,000 litres?" These and other matters should be aired in the debate to follow, and the new procedure should become better understood and refined in the process.

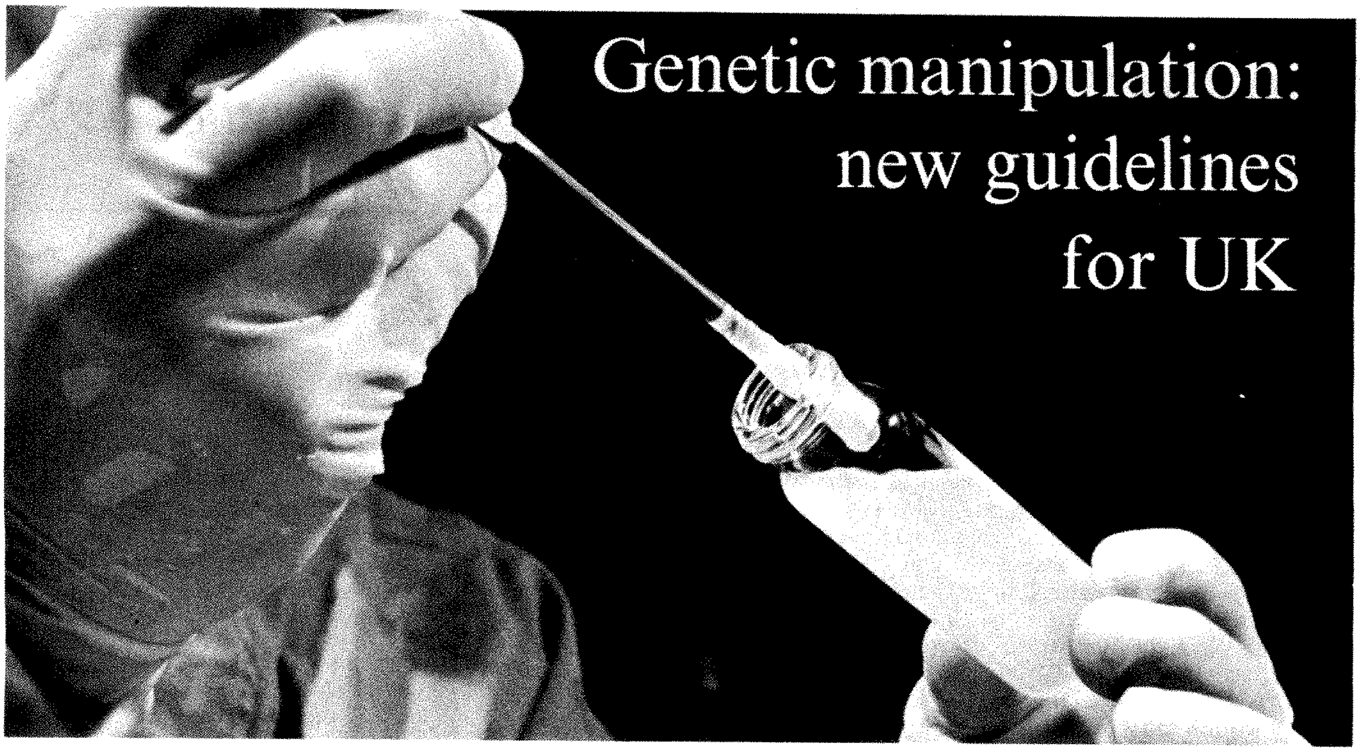
The second problem GMAG faces is international. GMAG—unlike the National Institutes of Health in the US—controls industrial research as well as academic work. So—certain industrialists argue—British firms will be penalised in the early stages of the potentially enormous business of biotechnology if GMAG's controls are any stiffer than those adopted voluntarily or by fiat elsewhere. It is important for industry that the controls on this research are internationally uniform. But the NIH guidelines, for example, take no care of what GMAG calls the 'expression factor'—whether the foreign gene is translated into protein or not. As industry clearly wants expression (that gives it its product) it is to industry's advantage that that factor is ignored. And this is just one example. To make such things uniform internationally is no easy matter, and it is important that it should be pursued at the highest government level.

International uniformity becomes a further cause why GMAG must make its procedures crystal clear. The European Science Foundation's Liaison Committee on genetic engineering adopted the earlier British (Williams) guidelines used by GMAG; but its members were lost in applying them to their own countries. What exactly were GMAG's internal procedures? And how could the smaller countries apply them, where there were too few researchers to set up a GMAG equivalent? The NIH system has won in many countries for its transparency—its lock-up table of containment—despite its evident logical shortcomings. Europe needs a European GMAG. Perhaps the ESF Liaison Committee itself could take on the role?

The third problem facing GMAG is the research on risks it so welcomely recommends. How is it to be done? Who is to do it? And who pays? Surprisingly, perhaps, the last question is the easiest to answer. Britain's Minister of State for Education and Science, Mrs Shirley Williams, interviewed last week on London Weekend television by MP Brian Walden, promised "tens of millions of pounds" for risk research in Britain. With that much, risk research might become like cancer research in the US: everybody will be doing it because the money is there. £10 million would certainly answer the previous question—who is to do it?

There remains the problem of careers for 'riskers'; as Brian Walden put it "there are no Nobel prizes for risk research". (Though who knows? One of the risks is of the escape of a bacterium producing large amounts of insulin, and no-one knows what such a bug would do. Another risk is of a bacterium expressing, say, cell surface proteins upsetting the immune system and inducing an autoimmune disease. Again, too little is known about the immune system to predict the consequences. Experiments on such matters might throw up new knowledge.) But if university researchers cannot be drawn away from their present interests what of the civil service scientists? What about those ex-Ministry of Defence people at Porton Down, now under Shirley Williams' control? Could they begin work on risk research?

Then there is also the problem of how risk research is to be commissioned. Surely GMAG should do that. GMAG has already expressed a willingness to do so, through the 'technical panel' GMAG recommends in its new proposals. And one final point. That panel should not consist entirely of academics, as its name appears to suggest. One of GMAG's strengths has been the breadth of interest represented by its members. It should not abandon that strength in what will become its inner sanctum. ☐



Genetic manipulation: new guidelines for UK

● Britain's Genetic Manipulation Advisory Group (GMAG) is preparing to adopt a new approach to assessing the risks of 'genetic engineering' experiments. GMAG's statement —approved in principle at a meeting on 2 November—appears below. The scheme is based on an attempt to assign numerical risks to individual experiments as a product of three factors: the 'access factor', the 'expression factor', and the 'damage factor'. But the numbers are used only to rank the risks so that the experiments can be assigned consistently to the containment categories I to IV. Qualitative matters are also taken into account, for biology has not yet been reduced entirely to numbers.

The scheme will be used when there are enough data to employ it; otherwise assessment will revert to the old Williams 'phylogenetic' guidelines. Its great virtue appears to lie in its objective scientific basis and its consequent encouragement to research on risks.

GMAG's Sub-Committee on the Validation of Safe Vectors* and, more recently, an *ad hoc* Working Party on Guideline Criteria†, have been considering on GMAG's behalf the merits of an alternative approach to the categorisation of genetic manipulation experiments first outlined by Dr Sydney Brenner (MRC Laboratory of Molecular Biology, Cambridge). GMAG, having considered the enthusiastic advice it has received, is persuaded of the general soundness of the new system, and subject to the consideration of comment on this discussion document and consultation with the Department of Education and Science and the Health and Safety Executive, hopes to introduce the new principles—to be used for the time being in parallel with the existing Williams Guidelines[1]—early in 1979. Before refining the system, GMAG wishes to take into account the opinions of the scientific community, and it is therefore hoped that publication of the following will allow all concerned to make their views known to the Group‡. In the very near future, GMAG will be arranging a meeting with users and with members of local Biological Safety Committees.

While seeing justification and opportunities for change, GMAG considers that there is no case for changing the general arrangements governing this area of research in the UK: the definition of genetic manipulation remains unchanged; the regulations[2] to notify work being done must apply; the roles of GMAG and HSE have been established; facilities for physical containment (categories I-IV) have been defined and substantial investment has gone into their construction.[3] Proposals are put forward in this paper, however, which if implemented would lead to change in the scientific considerations upon which the categorisations of individual experiments are decided by GMAG.

At present, GMAG broadly follows the Report of the Williams Working Party in allotting experimental protocols to the four categories of physical containment. The chief conclusion of the arguments which follow is that those experiments for which it is possible to carry out an approximate risk assessment should where appropriate be given categorisations distinguished by the labels I*, II*, III* and IV*. (It must be emphasised that no change is implied in the specification of physical containment facilities, but only in the *categorisation* of certain experiments.) It is suggested that the two systems of categorisation should persist in parallel for as long as may be necessary. At this stage relatively few experiments can be given the new starred categorisations, but a steady transfer of experiments and classes of experiments from one system to the other should be possible.

The Williams guidelines

Although in the past two years GMAG has based its advice on the "suggested categorisations" of the Williams Report, there have been several occasions when it has been necessary to modify or to extend that scheme. That this should have been so is not surprising, for the Williams Working Party reported when there had been very little practical experience of genetic manipulation. Moreover, the report explicitly acknowledged that its categorisations were likely to be found insufficient in some respects, and it

foresaw the need for refinement and substantial modification.

First, doubts have accumulated about the value of the criterion of phylogenetic relatedness as a measure of the possibility that genetic manipulations may be hazardous. A simple illustration will show the difficulty. According to the suggested categorisations, genetic elements from plants entail less relative hazard (to human beings) than genetic elements from higher organisms, yet it is also clear that the incorporation into the genome of a strain of *E. coli* viable in the human gut of a gene responsible for a plant immunogen (say the glycoprotein gluten from wheat germ) could be relatively more hazardous than a gene responsible for the production of, say, human globin. More generally, the bearing of phylogenetic relatedness on the potential dangers of experiments in genetic manipulation must be modified by the nature of the host and the vector; animal genes are, for example, less likely to retain their original functions when incorporated in the genomes of bacteria than in those of animal cells or viruses.

Second, the experience of the past two years has also shown that there is a need for a modification of the Williams prescription about the identity and the purity of transplanted genetic elements. Often the more relevant characteristic is whether the foreign gene is capable of being expressed (or otherwise retaining its original function). Moreover, evidence has accumulated in the past two years to suggest that many of the genes of higher organisms are distributed as separate pieces among the genetic material of the donor organism, which decreases the likelihood that shotgun experiments in which pieces of random DNA are transferred to other (and especially bacterial) hosts will yield functional genes in the new genetic environment. On the other hand, experiments in which genetic elements are obtained in potentially functioning form from functional molecules of messenger RNA, often regarded in the past two years as an assurance of their purity, may be in principle *more* potentially hazardous than the same genetic elements obtained directly from the genomic donor DNA. These statements are not, of course, of general application, but they are another reason to believe that individual cases should be dealt with separately.

Considerations of the host-vector system remain generally applicable. If there are hazards in any experiment in genetic manipulation, it will plainly be beneficial that a host organism carrying foreign genetic elements should be incapable of infecting human beings, and that the vectors used in the experiments should be specific to these host organisms. Appropriate use of "disabled" host-vector systems, offering "biological containment", will continue to be one of the essential features of certain types of recombinant DNA research.

More objective methods

In the circumstances, it is likely that all interested parties, scientists and the general public alike, would benefit if there were a more objective and even quantitative basis for assessing the risks of genetic manipulation. But it will be some time, perhaps several years, before biological understanding and quantitative data have accumulated sufficiently for such techniques to be applied to all proposals for experiments in genetic manipulation.

Elements of risk assessment

Assessment of the risk of experiments in genetic manipulation must follow a formal and comprehensive risk analysis, which is possible only when the biology of the host-vector system and of its interaction with the cells of organisms at risk is reasonably well known. At present the relevant biological data are not generally available, and many systems of potential value in genetic manipulation will therefore be excluded from the categorisation procedure now proposed. With the passage of time, however, it will be possible to include within the new basis for categorisation an increasing proportion of experimental proposals.

In general, risk analysis entails a consideration of the following steps.

(a) *Escape from containment*

The escape of organisms carrying foreign genetic elements from the containment specified for them is always a possibility, either because the facilities are not designed in such a way as to provide absolute assurance that organisms will not escape or because of some malfunction or accident. Thus it is proper to associate with each category of containment a specific probability (C_i, where i runs from I to IV) that organisms will escape. The quantities C_i have the units "probability per unit time per organism contained".

The ratios of these probabilities will be measures of the relative efficacy of the four different levels of containment, and there are at present only rough estimates of the ratio C_{IV}/C_I, the relative safety of the most stringent and the least stringent of the containment categories now in use. The ratio is likely to be less than 10^{-6} (corresponding to a factor of 100 for the interval between each category of containment) and may be less than 10^{-9}. It is important that the true range of safety offered by the four categories of containment should urgently be defined more precisely. On present indications, the range of efficacy spanning the least and the most stringent categories of containment is comparable with the degree to which the viability of some host organisms is reduced relative to the wild-type strains; this points to questions for the future about the relative protection from conjectured hazard of physical and biological containment.

(b) *Persistence in the environment*

The most direct concern in the assessment of the risks of genetic manipulation is that organisms carrying foreign genetic elements will gain access to the tissues of laboratory workers, but it is important that those concerned with the safety of genetic manipulation should consider the posibility that, as an intermediate step, organisms may lodge and even replicate in the laboratory into which they have escaped (as, for example, in culture dishes). In this and other parts of the analysis, care must be taken to identify all the possible circumstances in which organisms carying particular foreign genetic elements may be relatively at an advantage, so that the genes concerned are amplified and not attenuated.

(c) *Access to organisms at risk*

Organisms which escape as aerosols may be inhaled by laboratory workers or ingested, thus gaining access directly to the nasal tracts, the lungs and the gut. It is important that unfamiliar routes of access should not be overlooked—for example, the effects on human lungs of the inhalation of *E. coli* organisms carrying genes capable of producing, say, insulin are at present unknown.

(d) *Replication*

The risk analysis of experiments in genetic manipulation differs from that of, say, the operation of nuclear power plants in that agents which may potentially cause damage may in some circumstances be capable of replication. In the risk analysis of experiments in genetic manipulation, great care should therefore be taken to identify pathways that permit the replication of organisms carrying foreign genetic elements or which permit the transfer of the foreign genetic elements to other organisms which are capable of replication. One factor in a quantitative measure of a particular hazard would no doubt be provided by the duration and the intensity of the exposure of susceptible cels to organisms carrying potentially damaging genetic elements, and it is theoretically possible to calculate quantities such as these, given assumptions about the viability of manipulated organisms in the environments in which they lodge. Such formal calculations are however unlikely to be

Examples of the new categories

- The cloning of pure mammalian globin genes in an approved disabled *E. coli* host-vector system in circumstances in which the globin genes are not expressed would be I*. For the time being, the use of non-disabled strains of *E. coli* (including K12) or the expression of the globin genes in a disabled host-vector system would place the experiment in category II*. The cloning of expressible globin genes in a non-disabled host-vector system would, for the time being, be a category III* experiment. The allocations to these higher categories are justified by the present lack of certainty that the secretion of mammalian globin in the body tracts (including lungs and the genito-urinary tract) to which *E. coli* has access would be without risk. As this uncertainty is removed, lower categorisation may be considered appropriate.

Category I* is justified for the cloning of non-expressible globin genes in a disabled host-vector system on the following grounds—all three of the factors *A*, *E* and *D* are small (notionally less than unity). If it emerges that *D* is small even when globin genes are expressed, the experiments provisionally allocated to II* and III* might be reduced in categorisation.

This experiment may therefore be considered typical of those destined for Category I*. It should be noted that two of the three factors afford a measure of biological protection, and that in spite of the apparent innocuousness of globin, GMAG would probably be unwilling to agree that an experiment of this kind should be undertaken with wild-type *E. coli.*

- The cloning of genetic elements from the genome of the mouse with the use of defective polyoma virus as a vector, and with cultured mouse cells as hosts (with appropriate helper virus to facilitate the replication of the virus and the expression of functionable genes) would also

---

meaningful in present circumstances, so that more qualitative comparisons must at present suffice.

Great care must be taken to ensure that full allowance is made for the unavoidable incompleteness of present knowledge of the behaviour of foreign genetic elements in their hosts. Thus allowance must be made for the possibility that a "disabled" strain will revert (by genetic mutation) to the wild type, or that a foreign gene will be transferred (by the mobilisation of the plasmid) to wild-type bacteria. As things are, sufficient numerical data do not exist bearing on the chance that such events will occur, so that, for some time to come, researchers will have to rely on order-of-magnitude estimates of some of these quantities.

The conjectured hazards

Concern that genetic manipulation may entail hazards for living things stems from the possibility that foreign genetic elements may affect the normal functioning of particular groups of cells or the coordinated functioning of organisms at risk. Another of the impediments to formal and quantitative risk assessment that is likely to persist for some time is that of comparing the possible (but still hypothetical) biological consequences of foreign genetic elements with the damage done by naturally occurring disease. Even so, a tentative listing of some of the possible interactions between foreign genetic elements is suggestive of some of the points to which researchers should direct attention.

(i) Cell death

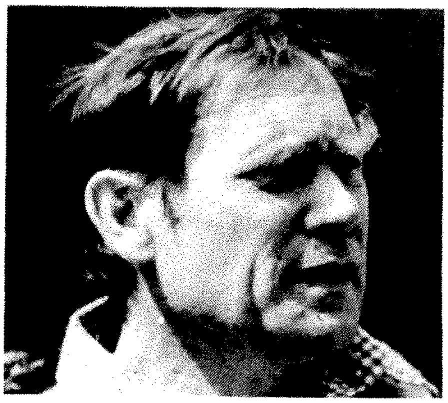
Cells may be killed when they are infected by viruses or when they are exposed to toxins produced by bacteria. Specific microorganisms and viruses often affect specific groups of cells in the body of a higher organism—poliomyelitis kills people because the poliomyelitis virus kills cells in the central nervous system when it has access to them, for example. In the analysis of the risks of genetic manipulation, the questions arise whether bacteria or viruses carrying foreign genetic elements are more virulent than the originals, whether the range of their specificity has been extended and whether bacteria carrying the intact genomes of pathogenic viruses make it possible for cells at risk to be exposed to potentially damaging viruses by unnatural routes.

(ii) Changes of genetic constitution

The introduction of foreign genetic elements into human somatic cells could have a number of harmful consequences. The state of differentiation of the cell might be affected. Cryptic viral elements already included in the DNA of the cell might be mobilised, or the foreign genetic elements themselves might be incorporated in the genome of the intact cell, increasing the range of cryptic viral function embodied in the cell. The chief causes of anxiety on such grounds have so far been in connexion with the occurrence of cancer, but understanding is far from complete. Experiments in which animal viruses multiply in human cells (in tissue cultures) without killing the cells may deserve special attention.

(iii) Immunological consequences

There are several hypothetical mechanisms whereby untoward immunological reactions might be provoked by foreign genetic elements. Thus foreign genetic elements might be incorporated in the genome of a human cell in such a way that the product of that gene (possibly a protein) was expressed on the cell surface, thus exposing the cells affected to attack by the body's immunological defences; this may correspond to the mechanism of some naturally occurring autoimmune diseases. On the other hand, the introduction of foreign genetic elements might be accomplished in such a way that their presence simulates that of the normal components of body tissues, with the result that the range of the sensitivity of the immune system would be narrowed. In principle, it is also possible that some of the cells of the immune system are especially vulnerable to organisms carrying particular genetic elements.



Sydney Brenner

(iv) Disturbances of endocrine function

Many hormones are believed to exert their physiological effects by interacting with specific biochemical elements either on cell surfaces or in the nuclear DNA. Foreign genetic elements could in principle interfere with either of these reactions, but it is also the case that infection by bacteria carrying genes which direct the synthesis of human hormones *and* which are expressed and then secreted into the body could be damaging to the individuals concerned.

(v) Disturbances of cell metabolism

Foreign genetic elements inadvertently introduced into somatic cells could in principle disturb the metabolism of these cells, changing their metabolic rate, the rate of cell division or even the process (still unknown) by which somatic cells age.

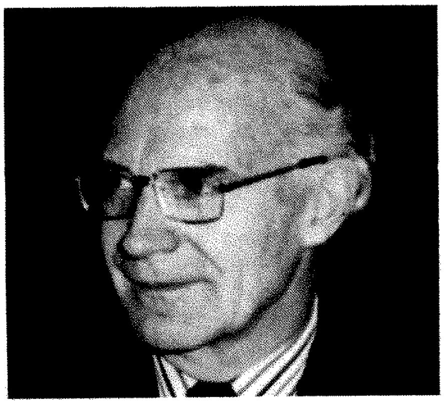
(vi) Consequences for microorganisms

Experiments in genetic manipulation in which bacteria might artificially be en-

0028-0836/78/0276—0106$01.00

be a category I* experiment. Formally, such experiments have much in common with those in which fragments of the *E. coli* genome are redistributed within the same organism with the help of *lambda* bacteriophage. In reality, however, the possibility that polyoma virus may replicate in cells other than those of the mouse cannot be entirely discounted (replication in rat cells has been demonstrated, while the possibility that polyoma might replicate in human cells has not been vigorously explored). Accordingly, the cloning of *pure* mouse genes in polyoma and cultured mouse cells is suggested as a category I* experiment, with mouse-genome shotgun experiments in category II* for the time being.

- Category I* will also include those experiments for which at present there is no substantial evidence of risk. The chief candidates of this kind are the experiments in which *E. coli* genes are cloned in *E. coli* organisms.
- If these illustrations are taken as a paradigm of experiments in category I*, then it would follow that disabled *E. coli* carrying but capable of expressing the gene for, say, wheat germ gluten would be categorised II* to allow for the possibility that at least some members of the population might react immunologically against the production of gluten in such a way. Other experiments that might be given the same categorisation on further consideration by the technical panel might include the incorporation of non-expressed interferon genes in *E. coli* K12, or expressed interferon genes in a more disabled strain of *E. coli* K12 (eg χ1776). Shotgun experiments with mouse DNA cloned in polyoma virus would also be included.
- Similarly, and again on further examination by the technical panel, category III* might include disabled *E. coli* strains carrying expressed human growth hormone genes; the expression of cholera toxin genes in disabled strains of *E. coli* would remain in category IV*.



Sir Gordon Wolstenholme

dowed with resistance to antibiotics of medical or veterinary importance are potentially hazardous. Another early suggestion of a damage mechanism is the possibility that apparently innocuous organisms (such as the laboratory strains of *E. coli* K12) could be converted by genetic manipulation into infectious pathogens; relevant in this regard is the conclusion of a conference held at Falmouth (New Hampshire, USA) in 1977 that *E. coli* K12 at least cannot be converted to an epidemic pathogen. There are three kinds of reasons for this conclusion: the gentic basis of pathogenicity is complex and does not reside in a single gene, the wild-type strains of *E. coli* which have evolved are probably in some sense optimal for the ecological niches they occupy and the viability of laboratory strains of *E. coli* is so much less than that of wild-type bacteria that such organisms carrying pathogenic elements would probably be eliminated rapidly. This conclusion does not imply that individuals could not be damaged by *E. coli* carrying pathogenic elements such as the gene for cholera toxin, but merely that the production of an *infectious* pathogenic agent is improbable. There is a need for a consideration along the same lines of other organisms capable of infecting human beings.

(*vii*) *Ecological consequences*
Similar considerations apply to the interaction of foreign genetic elements and species other than human beings. To the extent that species were differently affected and that foreign genetic elements were widespread, ecological changes are in principle possible. Changes in the ecological balance of microorganisms are perhaps especially important.

For those assessing recombinant DNA experiments, this list should make it possible to single out those kinds of interactions between foreign genetic elements and cells which are likely to be widely regarded as potentially serious and damaging. Possible immunological and oncogenic consequences point to the need for a relatively high category of physical containment.

Application in the immediate future

In an ideal world, it would be possible to make numerical estimates of the risk of experiments in genetic manipulation by multiplying together the probabilities representing the various events (*a*) to (*d*) (see page 105), summing over all possible pathways leading from the escape of a genetically altered organism from its containment to the causation of a particular consequence for cells exposed and then multiplying by factors which take account of the costs of the damage that results. This is not now possible, however. Some may even argue that it will never be possible or necessary.

Nevertheless it is possible to use the framework of this formal risk assessment to rank the relative risks of some experiments in genetic manipulation, albeit in a somewhat qualitative manner. To that extent, the arguments first put forward by Dr Sydney Brenner in the GMAG Safe Vectors Subcommittee are a valuable means of moving towards a more objective system of categorisation.

What is now proposed is that experiments with which researchers are familiar should be allocated to the four containment categories on the basis of a qualitative and relative assessment of their risks; and that the potential risks of novel experiments should then be assessed in relation to these familiar paradigm experiments.

For this purpose, it is convenient (as Brenner has argued) to define a group of three factors which may be taken to represent the chance that events following the escape of genetically altered organisms into the environment may lead to particular conjectured hazards. If data were available, it would then be possible to think of calculating the risk of an experiment by multiplying the numerical values of the three factors together. For the time being, however, such a procedure would provide a spurious sense of precision and it is proposed that there should be a comparison (which necessarily entails the exercise of people's judgment) of the values of the three factors relative to those which obtain for the paradigm experiments.

Analysis might therefore proceed as follows. First, it is supposed that there is an escape of organisms carrying foreign genetic elements. The overriding element in the assessment of the risk of a particular kind of disturbance is the likelihood that the organisms or the genetic elements they carry will have access to susceptible cells of the target organisms. Thus there is defined an

- **Access factor** (*A*). This is plainly a composite of factors representing the chance that escaped organisms will actually enter the human body, that they will survive there and that they will penetrate whatever membranes must be penetrated so as to reach the tissues containing susceptible cells. For many experiments, biological containment is dominant—for example the disabled strain of *E. coli* K12 known as χ1776 may be less viable than wild-type strains of *E. coli* by a factor of 10^8.

In some experiments in genetic manipulation, the potential risk depends crucially on whether the foreign genetic element is able to express its normal function. This would, for example, be the case in an experiment in which the gene specifying the cholera toxin was incorporated in a plasmid of *E. coli*. Thus it is convenient to define an

- **Expression factor** (E), which would be large (or notionally have the numerical value 1) if the foreign gene were efficiently translated into the protein product of the gene and if the products were then secreted from the altered organism, which would have a similar value in those circumstances (as for example in the carriage of a genetic element which can be integrated into the genome of target cells without being translated) but which would be small in those experiments in which steps had been taken deliberately to ensure that the gene would not be expressed.

Shotgun experiments require further consideration. The fear that "unknown" genetic elements might cause unknown and damaging changes in organisms at risk has been widespread for the past four years. The Williams Report suggested that experiments involving random lengths of DNA should be categorised somewhere in between the categorisation appropriate for genetic elements known to be damaging (eg cholera toxin) and those thought to be without risk. This conclusion remains valid, but knowledge of the genetic constitution of organisms is growing quickly, and for some it is now reasonably certain that a genetic element drawn at random is likely to be less of a relative hazard than one deliberately selected. This, for example, may be the case with many animal viruses, whose genetic structures appear to be so economical of DNA that it is hard to believe that a piece drawn at random would have physiological significance. Thus it is convenient to define a

- **Damage factor** (D), which expresses the chance that a genetic element will cause damage. D will be large (notionally, unity) if, for example, the host organism were known to contain a gene specifying a bacterial toxin; will be less if it is a genetic element drawn at random from the same bacterial genome; and will be very small if the product of the gene is known to be without physiological effect on the cells of the target organism (as may be the case where the gene product is, for example, human globin).

It is proposed that, in the months ahead, GMAG should take steps to allow researchers (if they wish) to submit their proposals to GMAG with evidence which will allow GMAG to make an assessment of the three factors and advise on the new basis. Given the present incompleteness of biological understanding and the lack of data bearing on the numerical determination of these factors, it is clear that, for the time being, decisions will continue to depend on judgment rather than calculation. It is also clear that experiments using familiar systems will be the most susceptible to this alternative treatment. One advantage of following such a course of action will nevertheless be to encourage the accumulation of data bearing on the ultimately more objective assessment of risks.

Proposals

The particular recommendations that follow are designed so as to achieve the following objectives. First, the intellectual framework of risk analysis should be used as a means of further refining the self-consistency of GMAG's present procedures. Second, GMAG's procedures should remain flexible, and be capable quickly of being adjusted in the light of new knowledge. Third, new criteria for deciding on categorisations should be applied at the outset only to the systems with which researchers are most familiar, with the expectation that, with the passage of time, increasing numbers of experiments will be included.

It is therefore proposed that GMAG should take the following steps as soon as this may be convenient:

1. The present Williams categorisations will be retained, and GMAG's present methods of assessment will be retained for experiments whose relative hazards cannot be assessed in the manner outlined above. But researchers will also be invited to ask that experiments should be given a different categorisation than suggested by Williams if they have reason to believe that in their case the factors A, E and D would justify such a course. Similarly, GMAG should be able to require more stringent categorisation in appropriate circumstances.
2. GMAG will set up a technical panel to scrutinise such applications on the alternative basis and to report to GMAG, to collect data bearing on a more thorough understanding and evaluation of the factors A, E and D, and to publish (through GMAG) to the scientific community advice on the continuing refinement of the procedure. Researchers might have to accept that, initially at least, these complementary procedures might entail some delay.

   In the first instance, it would be for applicants to provide such empirical data as they can on which the technical panel's consideration of the three factors would be based. It is hoped, however, that the technical panel would be a powerful stimulus of the research needed to make risk assessment more objective and widely applicable. Refinement of present knowledge of the relative efficacy of the different categories of containment may be thought an urgent need.
3. The proposed system must be grounded by the allocation of some paradigm experiments to the four categories of containment.
4. It is proposed that for experiments of the kind referred to in the box (item (*c*)), and for others in which the genes of *Bacillus subtilis* and *Pseudomonas aeruginosa* are rearranged, it should be open to laboratories to provide a block notification of a programme of experiments to be carried out over a substantial period of time, say a year. A condition of the acceptance of such a notification will be the inspection of the laboratory by GMAG, an undertaking to work in category I* conditions and to submit a report at some required interval (not less than a year) providing a detailed log of all experiments carried out. Laboratories working to such a block notification would be required to inform GMAG of all new workers in the laboratory, and of the transfer of organisms to other laboratories; but the use of such organisms in recipient laboratories could be carried out under conditions of good microbiological practice (PHLS Handbook No. 4). In due course, this category of experiments without discernible risk will no doubt be extended.

Acknowledgments

The credit for urging on GMAG the risk assessment approach to genetic manipulation and for drawing it first to the attention of GMAG's Safe Vectors Sub-Committee goes to Dr Sydney Brenner, whose cooperation in developing the system into its present form is also warmly acknowledged. GMAG also wishes to thank the Guideline Criteria Working Party for their work in drafting the present paper, and innumerable other experts who have generously given their advice. ☐

Top Scottish astronomer resigns after staffing row

Professor Vincent Reddish (above), director of the Royal Observatory, Edinburgh (ROE), handed in his resignation last week to the UK Science Research Council (SRC) which runs the observatory. When he relinquishes the directorship next September, he will also leave two associated posts, Astronomer Royal for Scotland and Regius Professor of Astronomy at Edinburgh University.

Professor Reddish's decision to resign has come after a prolonged dispute with the SRC over filling some senior posts, in particular that of head of technology. Administrators within the SRC would like to see the post go to an engineer. Reddish would like it to be given to an astronomer with some technological experience, who could interchange with astronomers at the observatory's other telescopes in Hawaii and Australia. The resulting deadlock has led to some posts remaining unfilled for years, according to Professor Reddish, and the lack of some senior staff is now beginning to impair the work of the observatory.

The SRC is trying to persuade Reddish to postpone or reconsider his resignation. It would like to readvertise the head of technology post inviting both engineers and astronomers to apply. The ideal candidate, according to an SRC spokesman, would be someone who is primarily an astronomer with a great interest in or some experience of associated engineering. Reddish feels that the reforms needed to make him change his mind are primarily too great for the SRC to implement. "In principle," he says, "the problem is essentially who decides how to do the work here and the kinds of skill needed to do it." In the event of no successful settlement, he plans to retire from astronomy altogether and move into business. ☐

Appleton and Rutherford to merge

At a meeting on 18 October, the Council of the UK Science Research Council (SRC) took the decision to close down its Appleton Laboratory at Slough and move it to the Rutherford Laboratory, also run by the SRC, at Chilton in Oxfordshire. The reasons for the merger are scientific, says the SRC. "Bringing these teams together would be the best way of doing their scientific work", according to Dr Brian Oakley, SRC Secretary.

The Appleton Laboratory is responsible for managing most of the UK's scientific space programme, which includes satellites, balloons and rockets, for scientists working in universities. The Rutherford Laboratory has always been the home-based focus of the UK effort in high energy physics at CERN. With the closure of its particle accelerator, Nimrod, earlier this year, however, it has had to diversify. It now houses a central laser facility, computing facilities and is building a central spallation neutron source.

The SRC hopes that two activities in particular, space work and radiocommunications, will benefit from the amalgamation of skills. At present work on both of these is done mainly at the Appleton Laboratory, although Rutherford has provided some engineering support for space projects in the past. Most recently, it helped design the stratospheric and mesospheric sounder for NASA's Nimbus-G satellite, launched towards the end of October. And it is currently working on the design of a millimetre wave radiotelescope with Appleton.

However some of the scientific staff at Appleton are far from content with the move. "The SRC came to a hasty decision without considering in sufficient detail all the points we would have liked them to" said Dr Jo King, Chairman of the staff side at Appleton. He feels there is little advantage to be gained from the move. Usually, he says, satellites are built in several different places and put together in one place. This would still have to happen even when the two laboratories merge. In the case of radio propagation work, Dr King claims that there will be too much radiointerference at Rutherford to make such work effective. "We are making very sensitive radio receivers" he says "and being asked to put them in one of the noisiest places in the UK".

The move is expected to take five years to complete. Appleton will be receiving data from the UK Ariel 6 satellite, to be launched next year, and the UK/NASA/Dutch satellite, IRAS, which will be launched in 1981. Final transfer to Rutherford therefore cannot be completed until those satellites cease to be operational. The bulk of the move will take place between 1980-83.

The engineering support at Appleton is weaker than that at Rutherford, according to Dr Geoffrey Manning, Rutherford's deputy-director, because it is the smaller of the two. When they are amalgamated, he says, it should be possible to provide laboratory support for all of the UK's space programme at one site. According to another SRC official, this should maximise the chances of the UK participating with the United States in the multi-mission refurbishable satellite (mrs)—a satellite proposal which has gained much support from the astrophysicists but little enthusiasm from geophysicists.

Judy Redfearn

Greater powers for Dutch science minister

The Dutch minister for science policy, Dr Marius Peijnenburg, has recently extended his role beyond that of coordinator. Together with one or two other ministers he now steers scientific research in government institutes and industrial laboratories. So far this has been the government's task.

With the minister for education and science, Peijnenburg will now be involved in decision-making at an early stage in university research as well as that carried out in the institutes of the Royal Netherlands Academy of Sciences. He will also be involved in formulating policy for the energy research centre, the aviation and space laboratory and the institute for aircraft development, which until now came solely under other ministers. Peijnenburg will also control TNO, the national organisation for applied research in the natural sciences. It has a staff of about 5,000 and an annual budget of £55m.

The 1979 research budget totals around £1.5 billion, 2.05% of the gross national product. More than £0.7 billion comes from government and £0.8 billion comes from industry (mainly from Philips, Shell, Unilever, Dutch state mines and AKZO). In 1978 and 1977 the research budget was £1.4 billion and £1.2 billion respectively. For the first time, the minister for science policy is to have his own small budget for stimulating new projects in areas such as systems analysis and technology assessment. It should increase to £3m a year by 1981.

In 1979 the time spent on non-nuclear research as a percentage of

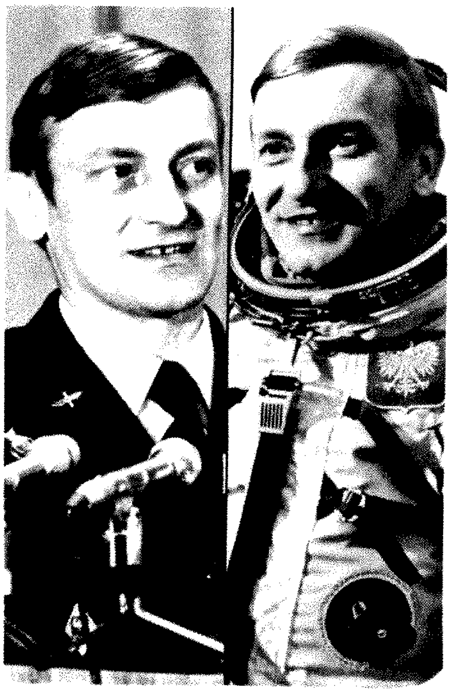
0028-0836/78/0276—0109$01.00

that spent on all energy research will increase from 36% in 1977 to 45% in 1981. Of the £57m spent on energy R&D in 1978, £30m is being spent on nuclear energy. Holland contributes £14m to the EEC energy research programme of which about £10m is spent on nuclear research.

Before the budget was published at the start of the new parliamentary year, the ministry for science policy announced that the Science Information Bureau will become permanent and be expanded slightly. It has been operating on a trial period for two years at the Academy of Sciences. And at a meeting of the special parliamentary committee for science policy at the end of October, the minister announced the setting up of a group of experts to study the effect of microelectronics, especially microprocessors, on society. The group should report within three months. **Casper Schuuring**

Poland tries the taste of space

During 1978, three cosmonauts from Eastern Europe visited the Soviet Salyut-6 orbiting space station. **Vera Rich** talks to the Polish cosmonaut, Miroslaw Hermaszewski in Warsaw



Two faces of Cosmonaut Hermaszewski; left—meeting the press; right, set for space.

MIROSLAW Hermaszewski, like his two brothers, is a pilot by profession, not a scientist. However as a cosmonaut he was obliged to fulfil a dual role—crew member and scientific worker. In the latter capacity Hermaszewski was responsible especially for space medicine, which he describes as "a Polish speciality".

The medical programme concentrated on two experiments: "kardiolider" and "smak". The first monitored the cardiovascular system "to determine the potentialities of the heart in space and also during pre-flight training". This, Hermaszewski told me, meant that "from the psychological point of view we felt very safe, knowing our hearts were being constantly monitored, especially when we were not in contact with Earth". (Constant contact, he explained, is not maintained as a rule, although Soviet ships around the world are on constant emergency watch.)

The second medical experiment "smak" (Polish for "taste") was designed by the Academy of Military Aviation Medicine to monitor sensory changes under conditions of weightlessness. A few days before take-off, the cosmonauts sampled various menus and chose those they wished to take into orbit. "We chose the meals we preferred" said Hermaszewski "but after a few days in space we didn't like them. This means that our sense of taste had changed."

Challenged that the falling off of appreciation could be due to deterioration of the rations and/or boredom, Hermaszewski explained that the meals were specially prepared to preserve quality and taste, and also that there was "a menu-cycle of six days". "And even then, it wasn't exactly the same meal", he added. "I mean, if on one day we had, say, *barszcz* and turkey at one meal, then six days later we'd have *barszcz* and turkey again, but not at the same meal." The scientific team who worked out the experiments had, he said, developed a numerical method of estimating taste, which allowed the activity of the taste-buds to be monitored quantitatively.

Both "smak" and "kardiolider", added Hermaszewski, were important for medicine in general. Versions of kardiolider were now being produced for use in post-coronary rehabilitation programmes, while "smak" could provide valuable data about sensory processes.

With the third main Polish experiment, 'Syrena', Hermaszewski clearly felt his responsibilities considerably. Although he worked in the experiment with the Soviet cosmonaut, Ivanchenkov—one of the long-stay Soviet crew—he was aware that the experiment had been developed by Polish scientists. "It was absolutely Polish from the beginning, and was called 'Syrena' after the symbol of Warsaw". He admitted that during the running of the experiment which took 5 to 6 hours each time, he kept getting up at night to check the equipment (apparently quite unnecessarily).

'Syrena' was in fact an experimental capsule, used in conjunction with the Soviet 'splav' furnace, to produce highly homogeneous tellurium cadmium and telkurium/mercury alloys. Such alloys, of substances with very different molecular weights, are of considerable interest in semiconductor technology, and, in fact, both the Czech and East German cosmonauts carried out analogous experiments. It appears from Hermaszewski's description, however, that although the Soviets provide the furnace, the various Comecon nationalities are responsible for the contents of the individual capsules and for working out the results—as well as for the symbolic code-name under which the experiment is performed.

This led, naturally, to the whole question of Comecon participation in manned space-flight. Hermaszewski stressed that, although he only knew the Czech and East German cosmonauts well—the other future crew-members arrived only towards the end of his own training—he felt confident that all the countries concerned (even Mongolia and Cuba) would have their own "concepts" to contribute to the programme. "But obviously that's their secret for the moment." He stressed, moreover, that there are a number of joint experiments in the programme, for example, some of the photographic surveys, and such things as the joint Polish-Soviet experiment on heat level.

As for Poland's future plans in space, he was noncommittal. It was beyond his competence, he said, to comment on the future of the *Interkosmos* manned programme, when the present series of joint flights is complete, or on the possibility of wider international cooperation in space, perhaps on a UN basis. He stressed, however, that "We are only at the beginning of the Polish space programme."

Fields of special interest for the future included: "cosmic technology ('Syrena' was an example of this); space physics; and experiments with some immediate effect on our economy — telecommunications, medicine, biology and so on".

As for his own future, Hermaszewski said that he is now doing a great deal of work with young people, including a special TV programme. "I have had a great many letters from the young people of our country, and they are all very proud that Poland has begun the peaceful exploration of space!" ☐

US slashes funds to WHO and other UN agencies

In a pre-recess move that caught administration officials off-guard, the US Congress has made reductions totalling over $27 million in next year's contribution to a number of key specialist agencies of the United Nations, including the World Health Organisation (WHO), the Food and Agricultural Organisation (FAO), and the United Nations Educational, Scientific and Cultural Organisation (UNESCO).

Furthermore the Congress has decreed that none of the remaining $200 million contributions to these agencies and the UN itself may be used for the purpose of "technical assistance". The agencies are now trying to work out whether they can accept contributions under such conditions; if not, then 25% of the budget of each which is currently provided by the US, has been placed in jeopardy.

Hardest hit has been WHO, to which the US contribution has been reduced by 43%, or $20.9 million; if this cut remains standing, the net result will be a 10% reduction in the organisation's total budget. Other cuts are: FAO reduced by $3.2 million (10.7% of the US contribution); UNESCO by $625,000 (2.1% of the contribution); World Intellectual Property Organisation by $110,000 (100% of contribution); and the UN itself by $2.85 million (2.5% of total contribution).

The decision to cut the contributions resulted from floor amendments accepted during debates in both the House and the Senate on the budget of the State Department, from which such payments are made. President Carter was unwilling to veto the whole bill, but while signing it into law he said that the amendment "compromises this government's ability to fulfil its legally binding financial obligations".

The President added that he intended to recommend the prompt restoration of the technical assistance funds and eliminate the restrictive language. Administration officials said last week that it was proposed to do this with a supplementary appropriations bill that will be presented as soon as the new Congress meets in January. However, even if the language is changed, it is unlikely that the money will be made available in time to meet the next payments to the agencies, due in February.

The cuts reflect growing concern by some of the more conservative members of Congress over contributions made by the US to international organisations over which they have minimal control; unlike "voluntary" contributions to institutions such as the World Bank, the size of which is related to voting power in the institution, the specialised UN agencies, to which contributions are assessed broadly on grounds of the ability to pay, operate on a one-country-one-vote principle.

"Voluntary" contributions come under the foreign aid bill; and this year Congress has attached to the bill conditions that prohibit its money being spent in countries such as Vietnam and Cuba of whose political regime it disapproves. "Assessed" contributions, however, although paid for out of the State Departments budget, are determined by international agreement, they are not supposed to be subject to the same type of pressures.

In previous years, attempts by members of the Senate to delete the technical assistance money from the department's appropriations and to transfer it to the foreign aid bill have been successfully resisted by the House. This year, however, caught up in the pre-recess rush of legislation, the House voted by 191 to 143 not to reject an amendment added by Senator Jesse Helms, whose cuts and restrictions subsequently passed into law.

"The use of assessed contributions to fund technical assistance is a device to tax the developed nations for the benefit of the undeveloped nations without proper consent from the developed nations", Representative John H. Rousselot, a former official of the right-wing John Birch Society, told the House in supporting the Helms amendment.

"It is changing the very nature of UN agencies away from programmes beneficial to all member nations and towards programmes of special interest to particular areas of the world."

David Dickson

Denmark expands research on Ante-natal diagnosis

The Danish government has taken a significant step towards including ante-natal genetic diagnosis in the general health service. It has approved a plan for expanding laboratories and research centres involved in ante-natal diagnosis and last month granted funds for making it available to all 'risk patients' within approximately five years.

In 1972 the Danish Medical Research Council (MRC) decided to support and coordinate the work of several laboratories on congenital deformities and metabolic diseases. In 1975 the Ministry of the Interior (MI) appointed a committee to investigate the extent to which ante-natal diagnosis should be developed in Denmark, to outline how it should be developed and, finally, to investigate its economics.

The MI-committee presented its report (MI-report 803/1977) in February 1977. It concluded that the community would gain considerably in both human and economic terms if ante-natal diagnosis was given high priority in the general health service.

The report considered chromosomal diseases and inbred metabolic disorders. The MI-committee estimated that about 4,000 chromosomal analyses would be needed yearly to check all risk groups —pregnant women older than 35 and those who have previously given birth to a child with a chromosomal disease. It recommended that seven centres specialising in aminocentesis—which is necessary for chromosomal analysis—be established. At present about 1,000 such analyses are done yearly.

Inbred metabolic disorders are very rare and diagnosis of each illness within this broad category requires its own special technique. Nevertheless, the report mentions several independent calculations which have found that for several specific diseases the benefit of ante-natal diagnosis and abortion in the case of positive results outweighs the cost. The main difficulty, however, lies with identifying those at risk. Either the whole population or selected groups can be screened. At present the Danish population as a whole is screened for phenylketonurea. The MI-committee has recommended that population screening is now extended to include congenital myxodoema.

Any further expansion of population screening for metabolic disorders must await the results of additional research. The MI-committee recommends, however, that programmes for selective screening should be incorporated into a few genetic research centres now. Centres should be established in Copenhagen and Aarhus, it says. They should coordinate all ante-natal biochemical diagnosis in Denmark. Six million kroner should be enough for about 2,000 such analyses a year—the current estimate of the need.

A communication from the National Health Service to all Danish hospitals, medical doctors and midwives marked the initiation of the new programme on 1 October. All pregnant women in Denmark belonging to a risk group are now offered genetic counselling and diagnosis. At the same time the financing of most prenatal genetic diagnosis will pass from the MRC to the general health service.

news in brief

● **Explosion hazard at Windscale:** An unexpected and potentially dangerous build-up of hydrogen in one of the storage silos at the Windscale reprocessing plant has forced British Nuclear Fuels Ltd to close the plant temporarily. The build-up of hydrogen was discovered on Tuesday, 3 October. Safety procedures were instigated to bring it quickly under control.

Hydrogen is produced by a reaction between the magnox cladding material that is stripped from irradiated fuel elements before they go into the reprocessing plant, and the water in which they are stored in the silos. The hydrogen build-up was caused by a sudden increase in the temperature in the silos, due to the settlement of the magnox; this speeded up the reaction.

The temperature was lowered when the stand-by cooling system was switched on. The hydrogen was dispersed by forced air ventilation of the silos, but this in turn caused a discharge of radioactivity into the area around the silo. Although the discharge was within the safety limits, people working in the area had to be evacuated and decanning (pictured above) and reprocessing procedures halted.

● **Austria decides against nuclear energy:** Austria's new nuclear power station at Zwentendorf near Vienna may never be used, even though it is already loaded with the necessary radioactive elements. This follows a referendum on nuclear energy in which the Austrian people voted by a small majority against the use of nuclear energy in their country. In the poll, 50.5% of the votes were opposed to nuclear energy, and 49.5% in favour.

The referendum puts the Austrian Chancellor, Dr Bruno Kreisky, in a difficult position. The Zwentendorf power station forms a major part of the government's energy policy, and the ruling Socialist Party now has to decide what to do with it. It could be converted to a conventional power station. Dr Kreisky, who has described the referendum result as "a personal defeat", has however announced that he will not carry out his threat to resign if the vote went against atomic energy.

● **"No scientific barriers to nuclear waste disposal" says US report:** Despite limitations, existing scientific knowledge and technology is adequate to proceed with selecting and characterising sites for the permanent disposal of radioactive waste, according to a report issued last week by the US Department of Energy.

The report says that the successful isolation of radioactive waste from the biosphere "appears feasible for periods of thousands of years" provided that a systems approach for selecting the geologic environment, repository site and waste-form is utilised rigorously.

And it says that a broad range of underground media, such as salt, basalt, granite and shales, should be considered to provide a "conceptual framework" for program planning and establishing near-term priorities.

The report was prepared by an inter-agency review group chaired by Dr John Deutch, director of the office of energy research. After 30 days for public comment, a revised version will be prepared for the President as the basis for an administration policy on the handling, transportation and storage of nuclear wastes.

It recommends that an executive planning council be set up as part of a partnership between the federal government and individual states to plan and implement the nuclear waste programme. And in order to assist in the progression to high level repositories, the report suggests that one or more intermediate facilities be established in several emplacement media and geologic environments "at the earliest practicable date." If an alternative to salt is selected for the first high-level waste depository, this is unlikely to be ready until 1992 at the earliest, the report says.

● **US and China agree to exchange research workers:** China is expected to send over 500 postgraduate students and research workers to the US over the next year under the terms of a verbal agreement made in Washington last week between the National Science Foundation and a visiting delegation from the People's Republic of China.

The most popular subjects are likely to be physical and biomedical sciences, engineering and applied technology. In exchange about 60 US researchers will visit China, although primarily to study subjects in the social sciences, language and literature, and archaeology and art.

In addition to these exchanges, many more Chinese students will come to take courses in the US through private arrangements with US universities; the first of these have already started courses at Stanford University and the University of California at Berkeley.

Under the terms of the agreement, which was reached after a two-week visit by the delegation which had included 14 universities and colleges, each side agreed to use "its best efforts" to fulfil requests for study opportunities, and to pay the costs for its participants.

● **Lund looks at UNCSTD:** How are preparations for next year's United Nations Conference on Science and Technology for Development (UNCSTD)? "Rather bad but not disastrous", says Docent Jon Sigurdson, director of the University of Lund's Research Policy Program and co-editor of the Lund Letter, circulated regularly to governments and people interested in UNCSTD. "There are organisational problems, and if the organisation doesn't work well we can't pinpoint the questions that should be discussed."

It is well known amongst officials working with UNCSTD matters that the UNCSTD Secretariat and the UN Office for Science and Technology have found cooperation difficult, with each one trying to make the conference its own show. Similar problems have arisen between the Secretariat and various UN agencies—UNESCO, for example—and UNCSTD's Secretary-General Da Costa, who has been on sick leave for extended periods, has not been able to provide the strong leadership necessary to bring the squabblers into line.

"The first phase of the preparations—the national analyses leading up to the national papers—is nearly over now", says Mr Lennart Båge of the Ministry of Foreign Affairs. "We are now anxiously waiting for the Secretariat to analyse these papers. As the third preparatory committee meeting has been postponed until January, we need good background documentation in good time for the meeting to make it an efficient starting-point for the international negotiations leading up to the conference."

The Research Policy Program is itself about to begin going through the sixty or so national papers to hand to see which themes they have taken up and where their deficiencies lie. "From what we have seen", says Docent Sigurdson, "most national papers seem to have dealt only with item one on the conference's agenda: science and technology for development. Very little attention seems to have been paid to the other three items, especially the last on: science and technology for the future".

Hormones and cell culture

from Philip S. Rudland

It is rare in science these days for a conference to be convened in memory of any one person, but such was the high regard in which Gordon Tomkins was held that the Sixth Cold Spring Harbor Meeting on Cell Proliferation* was convened in his memory in a field in which he was one of the father figures, that of Hormones and Cell Culture. Gordon Tomkins was one of the first to consider that animal cells in culture could be used almost like bacteria for following molecular events, and in particular the effects of hormones on various cell functions. Nowadays the Hormones and Cell Culture field seems to be split into two camps, one concerned with the isolation of growth factors and their mode of action on cell proliferation and the other with the action of hormones in inducing cellular differentiation.

Cell proliferation

On the cell proliferation side R. Iglesias (Santiago) emphasised the historical importance of hormones, particularly oestrogens, in inducing tumours in animals, although it is uncertain whether oestrogen usually affects cell proliferation directly as reported for a human breast cancer cell line (M. Lippman *et al.* National Cancer Institute, Bethesda), or through intermediary growth factors (estromedins) proposed and identified by D. Sirbasku *et al.* (University of Texas, Houston) as necessary for the growth of cells from some oestrogen dependent tumours *in vivo*. The major mitogens for cultured cells, the so-called growth factors, seem to be becoming purer and the purification of one from platelets was extensively discussed (R. Ross *et al.* University of Washington, Seattle; C. Heldin *et al.* Institute of Medical and Physiological Chemistry, Uppsala). A new growth factor of less than 3,000 daltons has been isolated from bovine pituitaries; this factor specifically stimulates the growth of a rat mammary epithelial cell line from a hormone-dependent transplantable rat mammary carcinoma (T. Kano-Sueoka *et al.* University of Colorado, Boulder). Vasopressin could act like a growth factor in 3T3 fibroblastic cells (H. Rozengurt, Imperial Cancer Research Fund, London). The importance of hormones and growth factors in promoting cell proliferation was emphasised when certain of these agents were reported to support the growth of several different cell lines in the absence of serum (J. Bottenstein *et al.* University of Calif. San Diego; Serrero *et al.* SPNCI, Nice; Lippman *et al.*). Cultured cells and tumours are also proving a rich source of growth factors. The discovery of growth factors was stimulated to some extent by the hypothesis that tumour viruses produced their transforming action on cells, at least in part, by the production of endogenous polypeptide growth stimulatory factors (G. Todaro, National Cancer Institute, Bethesda). Todaro now reported that a human fibrosarcoma released growth-polypeptides which could interact with receptors which normally bind a serum growth factor, MSA. Conversely however, normal rat or hamster liver released growth-promoting activity for virally, spontaneously and chemically transformed cells but which did not stimulate their normal counterparts (A. Lipton *et al.*, Hershey Medical Centre, Hershey).

Before discussing the action of growth factors further one needs to know how and where they act in the cell cycle. A. Pardee (Sidney Farber Cancer Institute, Boston) compared two different classes of model for the cell cycle which could account for the variability in the distribution of cellular intermitotic times, deterministic Gaussian types and random or probabilistic types. He suggested that a deterministic model giving a reciprocal normal distribution could be made to fit the daughter cell generation times as well as the semilogarithmic or first order plots of the probabilistic model, in contrast to a recent paper (Shields *Nature* **273**, 755; 1978) which claimed the contrary. However it seems that the choice between the two types of model at least is deterministic, depending on which side of the Atlantic the decision is made. Two slightly different versions of how growth factors affect the cell cycle were presented. First C. D. Stiles *et al.* (Sidney Farber Cancer Institute, Boston) considered that one growth factor, platelet factor, 'committed' quiescent 3T3 fibroblastic cells to a process which eventually led to a first order increase in the rate of cellular entry into S phase, while platelet-poor plasma was required to allow the cells to 'progress' to the increased rates of DNA synthesis. However L. Jimenez de Asua *et al.* (Friedrich Miescher-Institut, Basel) considered that the growth factors fibroblast growth factor and prostaglandin $F_{2\alpha}$ delivered both signals, one to commit the cells to change their growth rates and the second to increase the rate of entry into S. Hormones such as insulin and glucocorticoids alter only the second response.

Where do growth factors act?

The biochemical as opposed to the kinetic mode of action of growth factors is also unclear. Two models have arisen; the earlier envisaged that growth factors bind to cell surface receptors and then trigger intracellular 'messengers' without entering the cell; the more recent model considers that the growth factors are 'internalised' and go to 'control sites' inside the cell. Support for the earlier model was provided by the carefully controlled experiments of D. Cunningham *et al.* (University of California, Irvine) with the protease thrombin. He has found that this can still stimulate chick embryo cells' division even when attached to Sepharose beads which cannot enter the cell, although unattached thrombin was internalised (J. Quigley

Philip S. Rudland is a Staff Member at the Imperial Cancer Research Fund, London.

---

*Held on 29 August–3 September.

-0836/78/0276—0113$01.00

et al., State University of New York). A series of speakers starting with S. Cohen (Vanderbilt University, Nashville) showed that epidermal growth factor (EGF) could be internalised and eventually degraded in lysosomal vesicles. Whether internalisation of EGF is required for mitogenic activity, however, is unknown, although C. Fox (University of California, Los Angeles) found that the concentration of EGF required for half-maximal binding to the surface receptor was much less than for internalisation. The latter corresponded more closely to the concentration required to stimulate maximum rates of DNA synthesis, which suggested that internalisation might be the limiting step. Internalisation was not a unique property of EGF, however, since thyroid-releasing-hormone (A. Tixier-Vidal *et al.* Collège de France, Paris) and melanocyte stimulating hormone (A. Lerner *et al.* Yale University) are also internalised. If the first model for the action of growth factors is correct, there is a requirement for second messengers or a chain of messengers to continue the 'growth stimulus' inside the cell. A much simpler example of such a system is that of insulin control of a single enzyme, glycogen synthetase, in rat adipocytes (J. Larner *et al.* University of Virginia, Charlottesville). Two separate biochemical mechanisms were proposed to control a multiply-phosphorylated enzyme, glycogen synthetase. Phosphorylation of this enzyme and hence its activity were then controlled by a cyclic AMP-dependent protein kinase, a cyclic AMP-independent kinase and by the calcium-stimulated action of phosphorylase *b* kinase. Models of the first type for the action of growth factors may then involve biochemical pathways of nightmarish complexity.

Differentiation

Studies of the effects of hormones on differentiation processes emphasised the reciprocal nature of proliferation and differentiation. Thus in cultured adrenocortical cells, fibroblast growth factor inhibited steroidogenesis, the differentiation response, while ACTH, which stimulated steroidogenesis; inhibited cell proliferation (G. Gill *et al.* University of California, San Diego). The evidence that ACTH acts through cyclic AMP in this case was good since Y-1 adrenal cells could be selected which were deficient in some component of the adenylate cyclase in cyclic AMP-dependent protein kinase activities and these also failed to respond to ACTH (B. Schimmer *et al.* University of Toronto). Different inducing agents could also commit more primitive tissue culture cells (stem cells) to a new cell type. Thus vitamin A induced the formation of endodermal cells from mouse embryonal carcinoma cells *in vitro* (S. Strickland, Rockefeller University, New York), and dimethylsulphoxide (P. S. Rudland *et al.* Imperial Cancer Research Fund, London) and other agents (J. Lever, Salk Institute, San Diego) which induced Friend erythroleukaemic cells to synthesise globin, caused a rat mammary carcinoma stem cell line to differentiate into alveolar-like secretory cells. Interestingly the effect of hormones on the responsive cell in the animal may not necessarily be direct, but through other cell types. Thus during embryonic development the mammary rudiment of the male mouse regresses as a result of androgen action, not on the epithelium, but on the surrounding mesenchymal cells which in turn causes the epithelium to become necrotic (K. Kratochwil *et al.* Osterreichische Akademie der Wissenschaften, Salzburg).

The majority of the work on hormonal control of differentiation at the molecular level was concerned with the modulation of amounts of intracellular enzymes and secreted hormones in cells which were already differentiated, rather than changing the cell to a new type as above. Hormones mainly exert their effect on specific gene expression by increasing the amount of specific cytoplasmic mRNAs. Moreover in spontaneous rat hepatoma cell variants the control of the production of more than one gene product occurs at different, unconnected steps beyond the interaction of the glucocorticoid with its cytoplasmic receptor (E. Thompson *et al.* National Cancer Institute, Bethesda). In a *tour de force* of molecular biology J. Baxter *et al.* (University of California, San Francisco) first produced a working hypothesis that glucocorticoids rapidly modify chromatin structure (as measured by the binding of *E. coli* polymerase) in a gross way that nevertheless affects the expression of only a few genes in rat pituitary (GC, GH$_3$) cells, notably the growth hormone gene. He then reported the nucleotide sequences of the DNA complementary to human and rat growth hormone and human placental lactogen mRNAs, which were remarkably similar, and finally showed that a new protein containing immunoreactive growth hormone sequences could be obtained in bacteria by ligating cloned rat growth hormone cDNA and the ampicillin resistance gene of another plasmid. Thus the conference had come full circle from Gordon Tomkin's original belief in that a hormonally-regulatable gene from cultured animal cells could now be expressed in a bacterium. The conference ended with a highly enjoyable jazz session, a fitting tribute to Gordon Tomkins, the jazz musician. □

Antenatal diagnosis of genetic defects

from Bob Williamson

A NEW and most exciting method of antenatal diagnosis is reported in the *Lancet* (**ii**, 910, 1978) by Y. W. Kan and Andree Dozy, of the San Francisco General Hospital. They have applied recombinant DNA techniques developed to study the organisation of the human globin gene family, to diagnose successfully a fetus at risk for sickle cell anaemia. The method is very sensitive and safe and will no doubt be applied immediately in similar cases. However, the implications are far wider, for this result promises that any diseases for which a gene-specific probe can be identified may well be diagnosed in the same way.

As readers of these columns know, the arrangement of genes for which specific probes are available can be studied by restriction enzyme analysis to provide a detailed physical map of the coding and surrounding sequences. The human β globin gene occurs only once in the haploid genome, is separated from the related gene coding for the globin chain by some 7,000 base pairs, and contains at least one intervening sequence several hundred base pairs long. The map of restriction sites round the gene has been constructed by several groups, and there is broad agreement on its appearance (see *News and Views* **276,** 13; 1978). Kan has now shown that for people of white, black or Asian origin with no haematological disorder, there are usually sites for the restriction enzyme *Hpa*I generating a fragment 7.6 kb (kb=1000 bases) long and including the β globin gene. This was always the case for the whites and Asians tested. Blacks with sickle-cell anaemia have almost invariably lost the 3′ *Hpa* site, and a new one, which gives rise to a fragment 13 kb long is found instead. (Another restriction site giving a 7.0 kb β globin gene fragment is also occasionally found but this seems to be a polymorphism among blacks unrelated to sickle-cell anaemia). Natur-

---

Bob Williamson is Professor of Biochemistry, St Mary's Hospital Medical School, London.

0028-0836/78/0276—0114$01.00

ally, in general the cases with homozygous sickle-cell disease had a 'double dose' of the 13.0 kb fragment while heterozygous carriers had one 13 kb fragment and either the 7.0 or 7.6 kb fragment.

Sickle cell anaemia is due to a single base change in the DNA causing a substitution of valine for glutamic acid in position 6 of the β-globin protein sequence; this change presumably has nothing to do with events thousands of base pairs away. What seems to have happened is that the sickle cell mutation, which confers resistance to malaria in heterozygotes, just happened to occur in an individual who had either lost the site for *Hpa*I at 7.6 kb, or whose genes had undergone some rearrangement at that site. Then the rearrangement or change far away from the globin gene was 'fixed', to be locked in linkage to it in subsequent generations.

The fact that a second linked polymorphism has been found (and several have been suggested for the other globin genes as well) argues that these are rare but by no means unknown events. They may not occur often at any given site, but there is a likelihood (if one can generalise, as usual, from the globin genes to other structural genes) that several could be identified within a few thousand base pairs of any gene. Any mutation thus carries with it a characteristic detritus of surrounding gene material, in arrangement and sequence. This in turn implies that an advantageous mutation becomes 'fixed' more rapidly than random mutational drift occurs in unselected sequences.

One of the most remarkable aspects of Kan and Dozy's result is the sensitivity of the method. Only 15 ml of amniotic fluid were taken. There was sufficient DNA in the foetal cells suspended in this sample of fluid to allow direct analysis without further cell culture. DNA from the parents' white blood cells, and from any siblings, must also be prepared, to ensure that the linkage is valid in the case under study. Hybridisation and autoradiography take only a week, allowing a result to be obtained earlier than with methods that require a foetal blood sample, which must be taken later in the pregnancy. Termination can be offered in good time, and the investigation has none of the technical risks associated with taking a foetal blood sample, and does not require such sophisticated equipment.

By recombinant DNA techniques, the entire human genome can be easily cloned in lambda phage or in plasmids; at least four groups have done so already. These 'clone libraries' are being made available to groups wishing to study particular diseases and who have developed gene-specific probes. Consider, for example, identifying a similar linkage group for a condition such as haemophilia. Polysomes making factor VIII protein could be precipitated with antibodies, the RNA isolated and a DNA complementary copy cloned in a plasmid. This can be used to hunt for the gene sequence, and polymorphisms identified–attempts would be made to link these to the haemophilia mutation. If this can be done (and for a recessive illness, there are good theoretical reasons to think that it can) there is no need to look at the very small sequence change, often involving a single base pair, causing the disease—linkage is enough for antenatal diagnosis. Another advantage of the method is the ease of diagnosing heterozygotes—they will have one, but not both, genes affected—a pattern easily seen using restriction enzymes and hybridisation.

Several diseases will be candidates for this approach in the months ahead. Some cases of β-thalassaemia do not involve a gene deletion, but could be linked in a similar way to specific restriction sites, particularly where family studies are possible. It should be easy to develop gene-specific probes for single gene defects where the affected protein is known, such as agammaglobulinaemia, Tay-Sachs disease and Lesch-Nyhan syndrome. Even conditions where the protein affected is not yet identified, such as Duchenne muscular dystrophy, might be studied using recombinant DNA in this way.

Since it is often thought that this technology increases the overall abortion rate by making more knowledge available to parents, perhaps it should be noted that Kan and Dozy's case turned out to have the heterozygous sickle cell trait was not terminated, and will grow up haematologically normal. Far from leading to more terminations, the availability of accurate antenatal diagnosis for severe hereditary disease should allow a decrease in abortion, since parents can continue a pregnancy knowing that a child will be healthy rather than terminate all pregnancies for fear of a possible severe illness and death. □

Positrons at the centre of the Galaxy

from J. J. Quenby

AFTER a long struggle, balloon experiments seem to have established the presence of detectable γ-radiation due to positive electrons at the centre of our Galaxy. Whether this radiation is ultimately telling us about the remains of supernova explosions, the cosmic ray distribution, the physics deep inside the magnetic fields of pulsars or black holes remains a largely open question.

Positrons can react either in flight or at rest with electrons, bringing about their mutual annihilation and the production of two gamma rays at an energy of 511 keV. If the annihilation is at rest, a sharp 'line' flux of photons results but if the interaction is in flight, Doppler broadening of the feature spreads out the apparent frequency of photon emission. A sharp line is the characteristic signature sought by balloon-borne detectors used in γ-ray astrophysics. Even though the positrons responsible may be very slow, it is not necessary for all the annihilation radiation to produce a line. At low matter densities, normal in astrophysical situations, positrons and negative electrons may form a bound state known as positronium. 75% of all annihilations may occur in a 3-photon decay of this state, producing a wide spread of photon energies.

The earliest indication of line radiation from the galactic centre was obtained by Johnson, Harden and Haymes (*Astrophys. J.* **172,** L1; 1972) using a crystal scintillator with a resolution of ±24 keV. This group later improved their technique getting a resolution of ±11 keV (Haymes *et al. Astrophys. J.* **201,** 593; 1975). Both of these results gave line positions more than one standard deviation away from the 511 keV energy. A more definitive study has now been reported by Leventhal, MacCallum and Stang of Bell and Sandia laboratories (*Astrophys. J. Lett* **225,** L11; 1978) using a rather difficult technique involving cooled germanium detectors. A resolution down to 3 keV is achieved by keeping the solid state detector at around 100 K or less. One problem encountered by these workers was the instrumental background line at 511 keV due to cosmic ray interactions. However, by pointing on and off the source, a galactic centre 511 keV line flux of 1.2×10^{-3} ph S^{-1} cm^{-2} was found, together with some probable spreading due to the additional 3-photon decay mode. Against this confirmation of the Haymes group's work is a statement from the satellite experimenters on HEAO-1 that as yet no line flux around 500 keV is seen (HEAO-1 Newsletter 2, April 1978). Here again only a crystal detector with broad band energy resolution was used.

What explanation can be advanced

J. J. Quenby is in the Department of Physics, Imperial College London.

0028–0836/78/0276—0115$01.00

for the striking Leventhal *et al.* result? Positrons may occur deep within the magnetic field regions of pulsars, close to the surface, due to energetic proton reactions or indirectly from electric field acceleration of electrons. However, the strong gravitational field might be expected to significantly shift the line frequency from the 511 keV level.

For a long time it has been noted that radioactive decay products arising from nuclear burning at the time of supernova explosions may produce observable γ-ray lines (for example, Colgate, *Astrophys. Space Sci.* **8**, 457; 1970). The explosion is preceded by a silicon burning process in which reactions with free α-particles leads to the synthesis of elements near iron in the periodic table. In particular the decay of the ^{56}Co and the ^{44}Sc produced includes long half-line positron emission. Some fraction of the exploding star enters the interstellar medium. If the positrons come from this blown-off envelope, spatial and time variations are expected in the line flux.

Another approach to the explanation is to consider the interactions with the residual medium experienced by energetic cosmic ray particles in the Galaxy. In particular, particles above 10 MeV can excite positron emission from C, N and O atoms. Ramaty, Stecker and Misra (*J. geophys. Res.* **75**, 114; 1970) have made detailed estimates based on this mechanism but demand a cosmic ray energy density more than 10 times that seen near Earth. One way out of this problem is to realise that explanation of the 50 MeV γ-ray flux from near the galactic centre first seen by OSO-III (Kraushaar *et al.*, *Ap. J.* **177**, 341; 1972) may require a similar cosmic ray density enhancement.

Further information on the line emission should come when HEAO-C is launched, carrying a cooled germanium X-ray detector and also in the more distant future, from a larger version of this apparatus on board the GRO mission. It is then that the theoretical possibilities may be sorted out and other more speculative sources of positrons such as evaporating primordial black holes may perhaps be brought into consideration. □

Channels in membranes

from Venetia A. Saunders

THE latest applications of model membrane systems to the study of bacterial membrane function has provided an important insight into the role of the major outer membrane protein—matrix protein—and the mechanism underlying the action of the bactericidal colicin K protein.

The outer membrane of Gram-negative bacteria such as *Escherichia coli* is freely permeable to low molecular weight hydrophilic molecules such as glucose and amino acids (for a recent review see Di Rienzo, Nakamura & Inouye *A. Rev. Biochem.* **47**, 481; 1978). Recent results indicate that several outer membrane proteins have a role in the permeation of such molecules through the membrane.

Nakae (*Biochem. biophys. Res. Commun.* **71**, 877; 1976) has shown that incorporation of matrix protein (which corresponds to porin, molecular weight 36,500), a major outer membrane protein from *Escherichia coli*, into artificial membrane vesicles restores their permeability to a variety of saccharides. Such reconstituted vesicles show similar molecular sieving properties to those of the intact cell membrane. (Estimates of exclusion limits range from about 600 to 900 daltons for saccharides). It has been tentatively proposed that one function of matrix protein is to generate aqueous transmembrane channels that permit the rapid diffusion of small hydrophilic molecules. This notion is supported by the finding that mutants of *E. coli* lacking matrix protein are defective in passive diffusion (Bavoil & Nikaido *Molec. gen. Genet.* **158**, 23; 1977). There is also evidence (Schnaitman, Smith & de Salsas *J. Virol.* **15**, 1121; 1975) suggesting that matrix protein can be utilised as a receptor for the temperate coliphage PA-2 and that the amount of this protein is substantially reduced in lysogenised strains of *E. coli*. This could provide a mechanism for the exclusion of superinfecting phages. Ultrastructural studies of Steven and coworkers (*J. Cell Biol.* **72**, 292; 1977) have revealed that the matrix protein is present in a highly organised array within the architecture of the outer membrane: 10^5 copies of polypeptide per cell are arranged in a periodic monolayer which exhibits three-fold symmetry and triplet indentations (possibly corresponding to channels).

A recent paper from Schindler and Rosenbusch (*Proc. natn. Acad. Sci. U.S.A.* **75**, 3751; 1978) now describes the successful integration of matrix protein into planar lipid bilayers and shows that the incorporated protein creates voltage-controlled channels across these membranes. Those channels conduct ions and are freely permeable to small hydrophilic molecules. Analysis of the electrical properties of the membranes indicates that channels are induced irreversibly by voltage and that the number of channels is directly related to the matrix protein content of the membranes. Channels are proposed to be of uniform size, approximately 1 nm in diameter and to assume either an open (active) or closed (inactive) state. Schindler and Rosenbusch speculate that the closing of channels, which is favoured by high potentials, could be a mechanism for regulating permeability of the outer membrane. It is interesting to note that channel induction in the bilayers is voltage-dependent between *p*H 6 and *p*H 8, but is spontaneous at *p*H 10. The fraction of active open channels in bilayers at *p*H 10 is roughly equivalent to that in the bacterial cell, whereas the fraction of open channels in bilayers at physiological *p*H is significantly less. This discrepancy presumably reflects the inevitable artificiality of *in vitro* membrane systems.

In this issue of *Nature* (page 159) Schein, Kagan and Finkelstein report the use of planar phospholipid bilayer membranes to identify the precise mechanism of colicin action. They find that treatment of planar phospholipid membranes with colicin K also results in the formation of voltage-dependent ion-permeable channels, with the number of channels generated dependent on colicin concentration. These observations are consistent with the known effects of the E1 functional group of colicins (K, E1 and Ia) on the bacterial cell. They exert their bacteriocidal effects by a discharge of the 'energised state' of the cytoplasmic membrane and promotion of a net efflux of ions from the cell. One point of interest is that preparations of colicin K from *Proteus mirabilis* and *E. coli*, which are apparently specified by identical plasmids, differ somewhat in respect of their molecular weights and their quantitative effects on the artificial membrane system.

Schein *et al.* suggest that a single colicin channel could deplete a bacterial cell of all its potassium and other small ions within minutes. The relatively indiscriminate flux of ions through the channels could provoke at least partial depolarisation of the membrane. Since the energy to drive active transport systems derives from the transmembrane potential and the *p*H gradient (in accord with the chemiosmotic hypothesis), membrane depolarisation could in turn disrupt active transport. Indeed it is possible that depolarisation *per se* could lead to channel closure. The finding that E1 type colicins create voltage-dependent channels in artificial

Will detente kill millikelvin research?

from P. V. E. McClintock

RECENT exciting advances in physics at millikelvin temperatures have been made possible by an ample and relatively cheap supply of helium-3 for operating dilution refrigerators, but it looks very much as though this happy situation is now coming to an end, with an impending world-wide shortage of the gas. The Radiochemical Centre at Amersham, for example, is not accepting any further orders: even when the present backlog of orders, some dating back to the beginning of the year, has finally been cleared, it is apparently by no means certain that further supplies will become available for sale.

One of the principal uses of helium-3 is as the working fluid of the dilution refrigerators which have become the work-horses of millikelvin research. The principle on which they operate is extremely simple, just depending on the cooling effect which takes place when liquid helium-3 is allowed to dissolve in liquid helium-4. The refrigerator is usually arranged so that the process is continuous, with provision being made for separating the two isotopes again in a still, and for recirculating the ^{3}He back to the mixing chamber through a series of heat exchangers in which it is cooled by the cold dilute mixture leaving the chamber. Optimising the design of such machines is quite a complicated exercise, but progress over the past few years has been rapid: the refrigerators developed in Grenoble by Frossati, for example, are now able to sustain temperatures of around 2.5 mK in continuous operation, which is lower by a factor of four than the best available commercial machines of only a couple of years ago.

The present helium-3 famine arises, probably, for three main reasons. First, there has been a decided increase in the number of research groups building or buying dilution refrigerators, partly stimulated by the discovery of superfluidity in liquid helium-3 itself: all these machines require an initial charge of helium-3. Second, the relatively large machines which people are now tending to build require correspondingly large quantities of helium-3; this is particularly true of the Frossati designs, which incorporate exceptionally large diameter tubes within and between the lower heat-exchangers in order to reduce viscous heating effects as the liquid moves through the system. Finally, there is detente.

The ample supply of helium-3 enjoyed by cryophysicists in recent years has been produced as a byproduct of the nuclear weapons programme. The tritium used in thermonuclear devices decays through β-emission to helium-3, with a half-life of about 12 years. Although nobody seems very keen on discussing the exact arrangements made in practice for collecting the helium-3, one may infer that it is very much less convenient to do so once the weapon is in its final form ready for use, so that the ready availability of gas for sale to researchers and the cryogenics industry probably depends on continued manufacture.

Although the dilution refrigerator in its present form can certainly be regarded as a byproduct of the thermonuclear arms race, and any slackening of the latter must be warmly welcomed, it will be sad indeed if the excitingly rapid progress now being made in the millikelvin field is seriously curtailed. There are, however, two reasons to remain fairly optimistic about the long term outcome.

First, one may note that after being set up with its initial charge of helium-3, very little of the gas need get lost from a dilution refrigerator, such losses as there are occurring only by leakage or through human error, both of which can be minimised by careful design. So provided that there is a slowdown in the rate at which new machines are being commissioned, the present gap between demand and supply may eventually decrease again. Unfortunately there is no sign of this happening just at the moment.

Second, there always remains the possibility of extraction from natural helium-4, which usually contains a few parts in 10^7 of the light isotope. This certainly can be accomplished—at a price—and, indeed, was used as a small scale method of helium-3 production before the advent of extensive thermonuclear weapons programmes. There is a considerable variation in the helium-3 content of the gas from different wells. By choosing the right well and using modern isotopic separation techniques it just might be possible to produce helium-3 at a price not too much above the present £75 per S.T.P. litre. Furthermore, if the rumours about certain Polish gas wells prove to be correct—that they produce helium containing about 1 part in 10^5 of helium-3—a return to extraction from the natural helium could even lead to a reduction in the current price, at the same time making Poland the World's chief supplier of helium-3.

Until an alternative source of helium-3 is developed, detente is undoubtedly going to bring a measure of deprivation to the millikelvinists.

membranes is likely to provide a novel approach to the exploration of membrane function. ☐

Complexity and stability

from N. MacDonald

THE relationship between the complexity and the stability of an ecosystem has been debated for some years by mathematically inclined ecologists, and has occasioned the choice of title for an extremely influential book (May, *Stability and Complexity in Model Ecosystems*, Princeton, 1973). A possible relationship is indicated by a simple argument concerning a food chain, in which species A depends solely on species B, species B solely on species C, and so on. Any break in the chain eliminates all the previous members A,B . . . On the other hand, if there are alternative paths through a food network, one may expect the general structure of the network to survive the loss of one species. Here complexity is interpreted as the fraction of the pairs of species which directly interact, a quantity which may be termed connectance. Stability is interpreted as survival of all remaining species when one is lost.

As one makes the model more mathematically specific, so one has to be specific in the choice of a measure of complexity, and in the type of stability property that is studied. Some version of connectance, often allowing for an average over interactions of different strengths rather than simply counting the interactions, is usually the measure of complexity, in particular in a series of papers which appeared in *Nature* a few years ago. (Gardiner & Ashby, *Nature* **228**, 784; 1971; May, *ibid* **238**, 413; 1972; Siljak, *ibid* **249**, 280; 1974; Daniels & Mackay, *ibid* **251**, 49; 1974; Roberts, *ibid* **251**, 607; 1974; Gilpin, *ibid* **254**, 137; 1975; Saunders & Bazin, *ibid* **256**,

120; 1975.) Some criticisms of connectance as a measure of complexity can be found in another paper of this series (Somarjai & Goswami *Nature* **236,** 466; 1972).

From a philosophical point of view one may argue that it is paradoxical to seek a single index to characterise complexity. As argued by R. Rosen (*Int. J. Gen. Systems,* **3,** 227; 1977) the complexity of a system may involve the necessity of employing several parallel descriptions of the system. However connectance does pick out and quantify the intuitively satisfying notion that a collection of N solitary individuals is less complex than a collection of $N/2$ interacting pairs, and this in turn is less complex than a collection in which all the potential $\frac{1}{2}N(N-1)$ interactions take place.

The papers cited interpret stability as the stability of a steady state against small disturbances, that is to say they study the local stability of the equilibrium point of a dynamical system. Working with this narrow concept of stability the earliest of these papers showed that for components interacting at random, high connectance reduces the likelihood of stability. Later papers in the series incorporate restrictions on the interactions that seem obligatory if the system is to be acceptable as a model ecosystem. (For recent views of how this work may relate to observations on real ecosystems, see McNaughton, *Nature* **274,** 251; 1964; Pimm & Lawton, *Nature* **275,** 542; 1978.)

One way of going beyond local stability is by constructing Liapunov functions, which are analogous to the potential energy of a physical system. A recent book (Siljak, *Large Scale Dynamic Systems; Stability and Structure,* North-Holland, 1978) examines how the Liapunov stability of an ecosystem model is affected by the complete or intermittent removal of individual species. The criteria used for stability involve the diagonal dominance of interaction matrices. Thus it is required that individual populations are so stable in isolation that interactions with the other populations cannot destabilise. As the connectance increases, in the sense that interactions between species become stronger relative to the stabilising interactions within species, stability is lost. It is clear that the relevance of this to systems involving predation is remote. Some interaction between the predator species and at least one prey species is essential for survival of the predator. Another possible way of removing the restriction to local stability, with the implied reliance on linearisation of the model, is suggested by a recent paper in a rather different context (Froeschlé, *Phys. Rev.* **A18,** 277; 1978). The topic investigated is the relation between connectance and global behaviour of a certain set of formal transformations. The context of this work is the problem of the transition from integrable (periodic or multiply periodic) orbits to ergodic orbits in Hamiltonian systems, and in systems of formal transformations with area-preserving properties analogous to the Liouville property of Hamiltonian systems. Perhaps the most readable accounts of this problem are some reviews by J. Ford (for example in *Dynamical System Theory for Economists.* (ed. Szego) Springer-Verlag, in press).

Froeschlé takes N (up to 50) two-dimensional area-preserving mappings τ_i of a certain form and defines a multidimensional mapping T for which he can specify that T involves coupling between τ_i and τ_j for $j-i \leqslant N_c$. Thus N_c, which is taken $\leqslant 10$, is the connectance. It turns out that there is a sharp increase, at about $N_c=7$, in the extent to which ergodic orbits predominate. It remains to make a connection between the transition to ergodicity and the onset of instability. In practice the way in which one recognises the emergence of ergodicity is by computing the rate at which two orbits, initially very close, drift apart. This is linear with time for integrable orbits, but exponential for ergodic orbits. When using the local instability of an equilibrium point as the property to be interpreted as system instability, one is concerned with the exponential departure of a slightly disturbed orbit from that point. When one uses ergodicity as the relevant property, one is concerned with the rather more general feature of exponential separation of two initially close orbits. This would seem at least as good a candidate for 'the stability' of the system.

It remains to be seen whether the technical difficulties of investigating ergodicity allow one to work with systems satisfying the rudimentary requirements for a model ecosystem. Hamiltonian systems are well known, as discussed in May's book, to be unsuitable as model ecosystems. However it is now known, as reviewed recently in these columns (*News & Views* **271,** 305; 1978; **274,** 847; 1978) that behaviour analogous to ergodicity can arise in a much wider class of dynamical system. □

Informational suppression in higher organisms

from Peter Piper

MUTATIONS in one gene that correct specific defects in others can be isolated in many organisms and a knowledge of their mechanisms of action can throw considerable light on how various molecular components of the cell interact. A recent symposium on nonsense mutations and nonsense suppressors* reviewed ways in which an important class of these mutations, the so-called 'informational suppressors', partially correct certain defects in the protein-coding regions of structural genes by altering components of the protein synthetic machinery of the cell.

Mutations in the protein-coding regions of structural genes fall into different classes depending on the nature of the mutational change. In the deletion mutants a complete segment of the DNA is absent from the gene and this segment may include part of the protein-coding sequence. In another common class, missense mutants, a base substitution in the coding region of the gene leads to the substitution of one amino acid for another in the protein sequence. This alteration is selected on the basis of a change in the protein's properties, frequently a partial or complete loss of function, and can be corrected by the appropriate tRNA mischarging whereby the aberrent amino acid is replaced by another that restores functionality. Such mischarging can be induced by suppressor mutations in tRNA or aminoacyl-tRNA synthetase genes.

Nonsense mutations produce a base change in the sequence of a gene such that one of the three termination codons of the genetic code, UAG, UAA or UGA, is generated within the protein-coding region resulting in the synthesis of an incomplete polypeptide gene product. They can be reverted by suppressor mutations that allow insertion of an aminoacid in response to the nonsense codon. Similarly, frameshift mutations, which alter the reading frame of an mRNA by base insertions or deletions in the coding sequence can be reverted by suppressors that partially restore the reading frame during translation a short distance after it has been displaced by the frameshift mutation. Although nonsense and frameshift suppressors can be generated by mutation of genes for ribosomal proteins or tRNA modification enzymes, in bacteria and yeast where they have been biochemically characterised most of them arise by mutation of tRNA genes (J. D. Smith, MRC Laboratory of Molecular Biology Cambridge; F. Sherman, Rochester).

---

*Held at Aarhus University, Denmark on 9–21. July. Except where specified this article describes communications presented at the meeting.

0028–0836/78/0276—0118$01.00

More recently it has become possible to search for suppressor mutations in higher organisms by combining developments in the genetics of these organisms with advances in molecular biology that enable the precise nature of many structural gene mutations to be determined. In this way it is possible to show whether unlinked mutations that revert a particular genetic phenotype represent informational suppression or merely the activation of silent genes. Only a limited number of selective systems exist for the isolation of variant clones from mammalian cell cultures and as a result mutant cell lines can only be obtained with mutations at a small number of genetic loci.

One locus that has been extensively studied is that coding for hypoxanthine-guanine phosphoribosyl-transferase (HGPRT). Clones partially or completely deficient in HGPRT can be isolated by selecting cells resistant to certain purine derivatives such as 8-azaguanine (8AG) or 6-thioguanine (6TG). Good evidence exists that mutations in the gene for HGPRT are the basis of the changes in cell phenotype (C. T. Caskey, University of Texas, Austin; M. R. Capecchi, University of Utah, Salt Lake City). From these variants it is possible to isolate revertants that have regained the enzyme activity by selecting cells growing in medium containing hypoxanthine, aminopterin and thymidine (HAT) although this procedure only selects revertants having more than 40% of normal HGPRT activity, as shown by autoradiographic analysis of ^{3}H-hypoxanthine incorporation (J. E. Celis, Aarhus). As such it is not suitable for obtaining informational suppressors of mutations that inactivate the HGPRT gene, since these are unlikely to be able to restore the enzyme activity to such a high percentage of its normal level and not disrupt protein synthesis to a degree lethal to the cell. To be compatible with viability they will probably only restore the enzyme level to less than 20% of its normal value (Celis). The cell lines that can be shown to produce an altered HGPRT are only a small fraction of the variant clones resistant to 8AG and 6TG, and therefore this selection is not very efficient for isolating lines in which to study the process of mutation in animal cells or the structure-function relationship of HGPRT (Caskey).

Until recently it was impossible to verify the nature of the alteration in HGPRT defective clones, and so to classify these as missense, nonsense, frameshift or deletion mutants. However, this problem may soon be overcome. It has recently become possible to screen clones for the presence of nonsense mutations in the HGPRT gene by introducing nonsense suppressing tRNAs from yeast into the variant cells. These tRNAs are isolated from specific nonsense-suppressing yeast strains and have been characterised by their ability to suppress nonsense codons in *in vitro* protein synthesising systems (R. Gesteland, University of Utah, Salt Lake City). They can be introduced into mammalian cells either by direct microinjection using glass capillaries (Graessman & Graessman *Proc. natn. Acad. Sci. U.S.A.* **73**, 366; 1976) or, on a much larger scale, by being trapped within red blood cells which are then fused to the recipient cells (Kaltoft *et al. Proc. natn. Acad. Sci. U.S.A.* **73**, 2793; 1976). Preliminary experiments using the first procedure have shown, by autoradiographic measurement of ^{3}H-hypoxanthine incorporation combined with videotape recording of which cells were injected, that yeast nonsense suppressors cause a temporary phenotypic reversion when introduced into certain HGPRT-deficient cell lines (Celis). The second procedure can also be used to bring about *in vitro* suppression of nonsense codons (Capecchi) but is less readily applicable to the screening of many clones for nonsense mutants. It should also be possible to introduce frameshift suppressor tRNAs, isolated from frameshift suppressing strains of yeast, into variant cells, but these tRNAs may be too specific in their action to provide a selective system for the majority of frameshift mutants.

By fusing two mammalian cell lines, each carrying the same type of mutation but in different structural genes, it will be possible to isolate a hybrid cell carrying two identical mutations. In such a cell there will be a very low rate of simultaneous spontaneous reversion to the wild-type phenotype in both genes and the stage will be set for isolating the first true suppressor mutations of mammalian cells. Informational suppressors in higher organisms are already being characterised in *Drosophila melanogaster* and the nematode *Caenorhabditis elegans*. In the latter, Waterston and Brenner (*Nature* **275**, 715; 1978) have described a suppressor of the paralysed paramyosin-deficient E1214 mutant that acts on a range of alleles and partially restores paramyosin in worms homozygous for the mutation. The paramyosin synthesised as a result of the action of this suppressor seems to be identical to the wild-type protein. In *Drosophila* the existence of informational suppression is well characterised genetically, although in no single specific instance is the biochemical mechanism established.

Some disorganised muscle mutants of the nematode *Caenorhabditis elegans* produce a shorter myosin heavy chain than normal (A. R. MacLeod *et al. J. molec. Biol.* **114**, 133; 1977). After cyanylation of the wild-type and mutant proteins with ^{14}C-labelled cyanide, a reaction which breaks the myosins at their very infrequent cysteines and labels the N-termini of the fragments with ^{14}C, and gel fractionation of the products of partial cleavage of each of these fragments with cyanogen bromide, it is possible to distinguish nonsense and deletion mutants. In a nonsense mutant only the largest labelled fragment from one of the cyanylation products will have a reduced mobility relative to the fragments from the wild-type myosin, whereas in most deletion mutants several fragments show a diminution in size corresponding to the size of the deletion (S. MacLeod, University of Cambridge). Besides providing a way of mapping deletion mutants within the coding region, this approach can also be used to detect suppression of nonsense mutations in the genes for the heavy chain of myosin. □

Peter Piper works at the Imperial Cancer Research Fund Laboratories, London.

A hundred years ago

NEWS from Panama states that the volcano Cotopaxi is in a state of violent activity. Its crater is surrounded by ice and snow but the clouds of ashes and smoke rising from it can be seen even at Guayaquil on the shores of the Pacific.

A VIOLET coloured meteor, with a reddish train, was seen at Stanislas, Austria, on the evening of the 24th in the Great Bear and moving in a northerly direction. It is described as thrice the size of Jupiter.

. . . it is stated that carrier pigeons are "being turned to useful account" in a new direction in Germany, for Consul Ward writes to the Foreign Office "that the successful results attained by the establishment of communication between the two Eider lightships and the Port of Tonning, in Schleswig, by these means has led to its organisation" elsewhere. This mode of communication is, however, not new, as carrier pigeons were employed early in this country as a means of communication with the Bell Rock Lighthouse, as mentioned in my late father's "Account" of that work. The pigeons passed between the lighthouse and the shore—a distance of eleven miles in eleven minutes. The employment of these birds, however, was, I suppose, found to be more curious than convenient for they have long since ceased to be employed.

BOOK REVIEW SUPPLEMENT

Constraints on human behaviour

John Maynard Smith

On Human Nature. By E. O. Wilson. Pp.246. (Harvard University Press: Cambridge, Massachusetts, and London, 1978.) $12.50; £7.85

THIS, the author tells us, is "not a work of science; it is a work *about* science". Its thesis is that, in the coming period, the social sciences will be transformed by contact with evolutionary biology, in the same way as, in the immediate past, biology has been transformed by contact with chemistry. Human nature, like the nature of ants, hunting dogs or primroses, is the product of evolution by natural selection. It does not vanish with the appearance of culture, but remains as a constraint on the kinds of ways in which people can behave, and the kinds of societies which they can construct. Knowing this, he argues, it is both possible and useful to discover the nature of these constraints.

Like Wilson's earlier *Sociobiology*, the book is bound to arouse controversy; indeed, it is intended to do so. I hope that criticism will be of things Wilson does say, and not of things he does not. As most criticism will come from previously entrenched positions, it may help if I briefly describe my own. On many points I agree with Wilson. I do see recent advances in evolutionary biology, particularly in the field of behaviour, both as important in themselves, and as bound to give rise to renewed speculation about the relevance of biology to sociology. I do not think it sensible to see man as the behaviourists see him, a *tabula rasa* on which culture can write what it will. I do regard our higher faculties, such as our ability to construct mathematical arguments or to have religious experiences, as requiring an explanation in terms of natural selection.

Granting all this, however, I was not persuaded by Wilson's *Sociobiology* that biologists have all that much to contribute, for two main reasons. First, even if there are "human universals" which act as constraints on our behaviour, their nature will be discovered by psychologists and anthropologists; we biologists can only make encouraging noises from the sidelines. Second, human societies change far too rapidly for the differences between them to be accounted for by genetic differences between their members (Wilson, I think, would accept this). Hence, as differences are what we are primarily interested in, there is little an evolutionary biologist can say.

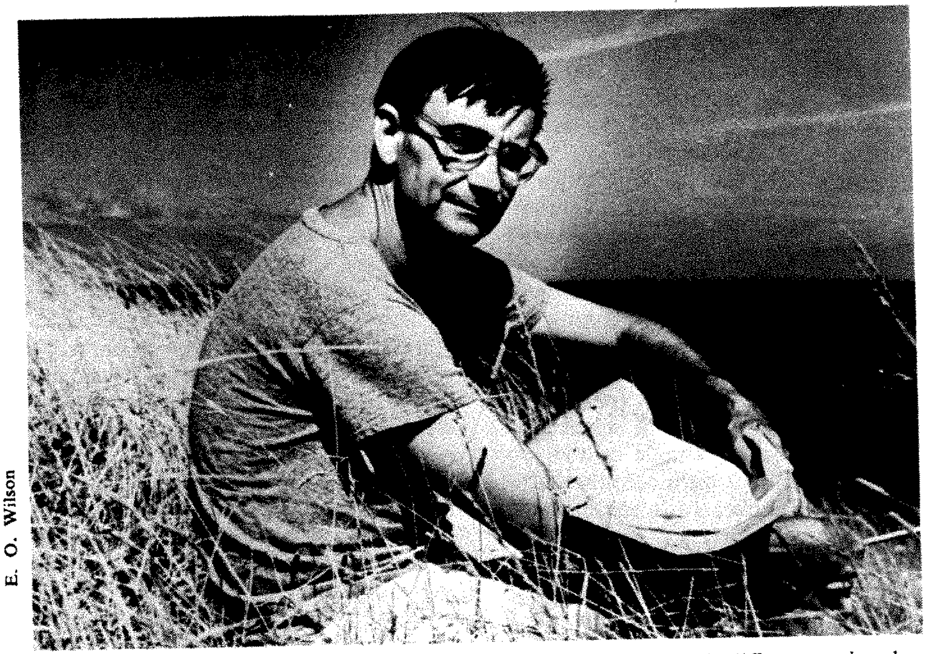
What, then, of *On Human Nature*? First, and most important, I found it entertaining and stimulating. I still have my doubts about how much progress can be made along these lines, but I would like to see it read both by students and professors of sociology. It would stimulate their imaginations to learn, on the one hand, that human societies represent only a sample of the animal societies that are possible, and on the other, that features of society they may have thought unique to man are found in other animals.

Wilson has defined his attitude to "genetic determination" more carefully in this book. Interestingly, he recommends Waddington's concept of canalisation as a paradigm for thinking about human nature and nurture. When he speaks of a trait as innate, he does not mean that it will develop in a fixed way regardless of the environment. He means only that a trait will develop in a rather constant manner despite wide changes in the environment, while accepting that a sufficiently drastic change in upbringing (or perhaps a sufficiently early one) might produce a profound change in outcome. By saying that characteristics are innate, he means only that we acquire some characteristics very readily and others only with great difficulty.

How then are we to recognise what is innate? Wilson reminds us that, classically, geneticists do not ask whether characteristics are genetically determined, but whether differences are. The difference between blue eyes and brown is genetic, and between speaking English and French is not, but it is meaningless to ask whether eyes or languages are genetic or environmental, as both require both genes and an environment. This has seemed to me a serious difficulty with the search for innate human universals. Wilson's answer is that we can look at the difference between all humans on the one hand, and all chimpanzees, say, on the other. Thus, if most human beings avoid committing incest this can be regarded as innate, because there are other animals (not, as it happens, chimpanzees) which regularly do commit incest. The fact that incest does occur in our species does not prove that there is no genetically determined tendency to avoid it, because Wilson is not using the term "genetically determined" to mean "certain", but only "likely in most environments".

This attitude can be further illustrated by his chapter on aggression. It opens "Are human beings innately aggressive? This is a favourite question of college seminars and cocktail party conversations, and one that raises emotion in political ideologues of all stripes. The answer to it is yes." Now the reason this opening raises emotion in political ideologues (including this one) is that it will be taken to mean that human beings are aggressive come what may, that war is inevitable, and that it is therefore a waste of time to work for peace. But it turns out that Wilson does not mean anything of the kind. By saying that we are innately aggressive, he means only that we have shown aggressive behaviour, including warfare, in most, but not all, of the cultural environments in which we have so far found ourselves. He emphasises that the word aggression has been used to describe many disparate patterns of behaviour. He ends the chapter with a discussion of how we might circumvent our tendency to be violent towards one another. Given that these are his views, I think that the opening words of the chapter are unfortunate. They will certainly provoke controversy, but it is likely to be of that singularly useless type which takes place between people who do not understand one another. Rather than speak of traits being innate, it would be more sensible to ask: What are the circumstances, genetic and environmental, in which a particular trait appears, and how can it be modified?

Wilson's attitude can perhaps best be illustrated by his treatment of human sex differences. All known human societies show some economic sex role differentiation, which shows considerable bias, in that some roles (for example, making tools) are performed in most societies by men, and others (for



E. O. Wilson

Photo: D. I. Crossley/AP

example, making pots) by women, although the bias is never absolute. Both the role differentiation and the bias in it call for an explanation. There seem to be two possibilities. The first is that there is a physical difference between men and women (women bear and feed babies; men are stronger and swifter) and the roles adopted are a direct consequence of this. The second is that there are innate cognitive and temperamental differences between men and women predisposing them to these roles. As technology is reducing the importance of purely physical differences, it would be easier to abolish role differentiation, should we so wish, if the first hypothesis is true.

Wilson's position, in brief, is that there probably are slight cognitive and temperamental differences between the sexes, but that sexual exploitation has been exaggerated as society has become more complex. He makes it quite clear that whether such differences exist or not need not determine our aims in present-day society. We could choose to exaggerate existing differences, or to give equal opportunity (in which case, he believes, we would not achieve statistical equality in role performance), or we could deliberately aim at statistical equality. Thus, he makes it clear (as was not clear, at least to me, in *Sociobiology*) that he does not subscribe to the view that what evolution has produced is morally right.

In general, his attitude seems to me sensible. The physical differences between the sexes are clearly a product of natural selection, and provide a clue to the breeding system of our recent ancestors. As an evolutionary biologist, I would find it odd if there were not also psychological differences; if economic role differentiation is ancient, as it may well be, then selection favouring a psychological difference is also ancient. Wilson offers two types of evidence for such innate differences. One, that girls exposed to masculinising hormone in the womb often behave in ways more typical of boys, is relevant and suggestive. The other, concerning behavioural differences between small children, is less persuasive; even if children are treated alike, they know their own sex, and will imitate adult behaviour.

This book will arouse controversy on many separate issues. Some will criticise it on the grounds that any emphasis on man's biological nature will be used to defend the *status quo*. I think such criticism mistaken. Women have been monstrously misused; it is natural that many of them are angry and frustrated. But the cause of women will not be helped by refusing to think dispassionately about the nature of sex differences.

There are many other issues. To what extent is a causal, scientific approach—whether sociobiological, Marxist, functional or whatever—appropriate to the analysis of human affairs? If the religious faculty, like the excretory, is a mere product of natural selection, where can we look for the basis of our moral beliefs? To me, the most interesting question is how far evolutionary biology can contribute to the human sciences. As I have explained, I am a doubter. But I have been wrong on this issue before. Ten years ago I regarded incest avoidance as an entirely cultural phenomenon; only a bigot could hold this view today. I hope Wilson's book will be read and debated; I hope, too, that during the debate each side will listen to what others are saying. ☐

John Maynard Smith is Professor of Biology at the University of Sussex, UK.

Rejoicing in multifarious nature

Richard Dawkins

Ever Since Darwin: Reflections in Natural History. By Stephen Jay Gould. Pp.285. (Burnett Books/André Deutsch: London; Norton: New York, 1978.) £5.50.

"The author shows us what is revealed when we remove the blinkers which Darwin stripped from biology a century ago." Some overkill there, or an excitingly paradoxical striptease technique? The first essay in the book discusses Darwin's own coyness in not revealing his theory until 20 years after he thought of it, and I shall return to this. The quotation from the jacket blurb gives a false impression, for Stephen Gould's writing is elegant, erudite, witty, coherent and forceful. He is also, in my opinion, largely right. If there are elements of paradox and overkill in Dr Gould's intellectual position they are not to be found within these covers. *Ever Since Darwin* is a collection of essays which first appeared as a regular monthly column in a magazine called *Natural History*. Skilfully edited to flow in eight main sections, the 33 essays, of which I can mention only a sample, reinforce my feeling that scientific journalism is too important to be left to journalists, and encourage my hope that true scientists may be better at it than journalists anyway.

Gould's collection begins to bear comparison with P. B. Medawar's immortal *The Art of the Soluble* (Methuen, reprinting). And if his style does not quite make the reader chortle with delight and rush out to show somebody —anybody—the way Medawar's does, Gould is to be thanked for some memorable lines. No doubt puritan killjoys of Science for 'The People' will denounce the vivid and helpful anthropomorphism in "Reproduce like hell while you have the ephemeral resource, for it will not last long and some of your progeny must survive to find the next one" (p94). But on second thoughts they may be too busy plotting the abolition of slavery in ants (p265), or brooding over the deviationism of "Natural selection dictates that organisms act in their own self-interest . . . They 'struggle' continuously to increase the representation of their genes at the expense of their fellows.

Prentice Hall International

books for the psychologist:

Physiological Psychology Second Edition Marvin Schwartz
Animal and human research underpin the findings of this revised edition, which shows the physiological basis of our behaviour. Sleep and wakefulness, hunger and eating patterns are some of the processes explored. **1978 496*pp* £11.65**

Reflections on Behaviourism and Society B. F. Skinner
A collection of papers published in the last five years by one of the major figures of modern behaviourism, this shows Skinner at his provocative best: discussing education, ethics, Walden One and Two, and the current fascination with the paranormal and the irrational. **1978 250*pp* £11.65**

Experimental Psychology: A Methodical Approach Third Edition F. J. McGuigan
Reveals the logic of experimentation from the creation of a problem and the choice of a design to the analysis of data and the implications of results. Quasi-experimental methods and research ethics are not overlooked. **1978 384*pp* £10.20**

THESE LECTURE AND REFERENCE textbooks are available to qualified teaching staff in the U.K., for examination and possible adoption. And that, for all its baldness, is all there is to it; we have discovered no higher principle in nature" (p261). My only recurrent complaint against the style concerns the journalistic adjectival phrase before names: "English biologist J. B. S. Haldane probably anticipated every good idea that evolutionary theorists will invent this century".

Ever since Darwin we have known why we exist and we have known at least how to set about explaining human nature. I agree that natural selection is "the most revolutionary notion in the history of biology" (p23) and I would toy with substituting 'science' for 'biology'. Childishly simple as it is, nobody thought of it until centuries after far more complicated ideas had become common currency, and it is still the subject of misunderstanding and even apathy among educated people. A microcosm of this historical enigma is the subject of Gould's first essay. Just as humankind waited centuries longer than our hindsight deems necessary before discovering natural selection, so Darwin delayed his own publication 20 years after he first thought of the theory in 1838. Gould's explanation is that Darwin was afraid of the psychological implications of his idea. He saw, what Wallace would never admit, that the human mind itself must be a material product of natural selection. Darwin, in fact, was a scientific materialist—a biological determinist. And we know how biological determinists can expect to be treated by their colleagues. No wonder he delayed publication.

In another essay Gould is encouraged by the genetic closeness of humans and chimpanzees to speculate that "inter-breeding may well be possible". I doubt it, but it is a pleasing thought and Gould surely exaggerates when he rates it "the most . . . ethically unacceptable scientific experiment I can imagine" (p54). For my ethics, far less acceptable experiments are conceivable, and actually done in animal physiology laboratories every day, and a chimp/human hybridisation would provide exactly the come-uppance that 'human dignity' needs. Gould is, in general, rather good at puncturing human speciesist vanity, and in particular he will have nothing to do with the myth that evolution represents progress toward man. This scepticism informs his valuable account of "Bushes and ladders in human evolution", and fires his scorn for attempts to rank human races as primitive or advanced. He returns to the attack on progress in the very different guise of the theory of orthogenesis, the idea that evolutionary trends have their own internal momentum which eventually drives lineages extinct. His telling of the classic Irish Elk story gains freshness from his intimacy with the fossils of the Dublin Museum and gives the lie to the myth that palaeontology is dry and dull. His conclusion that the proverbially top-heavy antlers were important in social life is surely right, but he may underestimate the role of within-species competition in driving species extinct. Large antlers could directly have caused the extinction of the Irish Elk while, at the same time, right up to the moment of extinction, individuals with relatively large antlers were out-reproducing individuals with relatively small antlers. I would like to see Gould come to terms with the "orthoselective" impact of "arms races" both between and within species. He seems to approach this in his essays on the "Cambrian explosion".

Ooh-ah biology can be sold for its intrinsic fascination, but it is much better used to make a point. Gould tells us about a fly that eats its mother from the inside, about seventeen-year cicadas and 120-year bamboos, and about uncanny fish-decoying mussels. He employs the useful trick of first opening the reader's mind by boggling it, then filling it with an important biological principle. One principle I would like to have heard more on is that of the limitation of evolutionary perfection: "Orchids are Rube Goldberg machines; a perfect engineer would certainly have come up with something better" (p91; Rube Goldberg is the American Heath Robinson). My own favourite example, inherited from an undergraduate tutor, is the recurrent laryngeal nerve. It starts in the head, goes down into the chest, loops round the aorta, then goes straight back into the head again. In a giraffe this detour must be wasteful indeed. The human engineer who first designed the jet engine simply threw the old propeller engine out and started afresh. Imagine the contraption he would have produced if he had been constrained to 'evolve' his jet engine by changing a propeller engine one bit at a time, nut by nut and bolt by bolt! While on the problem of perfection, I think Gould exaggerates the relevance of 'neutral mutations'. Molecular geneticists are understandably interested in DNA changes as molecular events, and any that have no effect on protein function may reasonably be called neutral mutations. But to a student of whole organism biology these are less than neutral: they are not, in any interesting sense, mutations at all! If the molecular neutralists are right, their kind of neutral mutation will for ever be hidden from the field biologist and from natural selection. And if a field biologist actually sees variation in phenotypes, the question of whether

DEVELOPMENTS IN AGRICULTURAL AND MANAGED-FOREST ECOLOGY

Volume 2:
TREE ECOLOGY AND PRESERVATION
by A. Bernatzky

This well-illustrated book (containing over 225 illustrations) deals with two major topics - the ecology of trees and a review of the measures available for their preservation. The effects of trees on man and his environment are also considered. The approach of the book is practical, reflecting the author's lifetime experience of working with trees.

1978 viii + 358 pages ISBN 0-444-41606-4
Price: US $65.25/Dfl. 150.00

Volume 3:
CYCLING OF MINERAL NUTRIENTS IN AGRICULTURAL ECOSYSTEMS
edited by M. J. Frissel

Based on invited review papers supplemented by discussions of international specialists, this volume gives a worldwide survey of the current state of knowledge in this important field.

1978 viii + 356 pages ISBN 0-444-41660-9
Price: US $39.75/Dfl. 95.00

Volume 4:
INTERACTIONS BETWEEN NON-PATHOGENIC SOIL MICROORGANISMS AND PLANTS
edited by Y. R. Dommergues *and* S. V. Krupa

Containing contributions from a number of international experts, this book considers the interactions between non-pathogenic soil microorganisms and plants within the framework of the whole soil-plant-atmosphere system.

1978 xii + 476 pages ISBN 0-444-41638-2
Price: US $86.75/Dfl. 195.00

Volume 5:
ECOLOGY OF ROOT PATHOGENS
edited by S. V. Krupa *and* Y. R. Dommergues

An up-to-date summary of the present state of knowledge with regard to the major categories of soil-borne plant pathogens, including a discussion of the new and exciting approach of biological control of root disease.

In preparation Expected December 1978

Volume 6:
SOIL DISINFESTATION
edited by D. Mulder

This multi-author volume presents a review of the various methods of soil disinfestation (physical, chemical and biological) currently available, considering both their effectiveness and possible deleterious effects of their use.

In preparation Expected December 1978

Previously published...
Volume 1:
PLANT MODIFICATION FOR MORE EFFICIENT WATER USE
edited by J. F. Stone

"... a valuable addition to the personal library of both soil and plant scientists interested in plant water relationships."

Independent Opinion by Five of the World's Leading Organic Chemists

COMPREHENSIVE ORGANIC CHEMISTRY

The Synthesis and Reactions of Organic Compounds

Chairman and Deputy Chairman of the Editorial Board
SIR DEREK BARTON, FRS & W. DAVID OLLIS, FRS

Extracts from Tetrahedron:

LORD TODD, PRS Cambridge, reviewing Volume I (Stereochemistry, Hydrocarbons, Halo Compounds, Oxygen Compounds; edited by J.F. Stoddart, Sheffield):
"I confess that I have been much impressed by Volume I, largely, of course, because it meets my criteria for a personal reference text for the practising organic chemist .... If the other five volumes adequately match the first then **Comprehensive Organic Chemistry** *will fill a long-felt need and should be a success."*

G. OURISSON, Strasbourg, reviewing Volume 2 (Nitrogen Compounds, Carboxylic Acids, Phosphorus Compounds; edited by I.O. Sutherland, Liverpool):
"The present volume is probably typical of the complete series. It is 'medium-sized', has a very wide coverage, relies heavily on existing reviews and books, and is definitely up-to-date .... I am convinced that the emphasis is right; that the book, and certainly the series, will find daily use in most organic chemical laboratories, for quite a long time."

G. STORK, New York, reviewing Volume 3 (Sulphur, Selenium, Silicon, Boron, Organometallic Compounds; edited by D. Neville Jones, Sheffield):
"Judging by this volume, which I take to be representative of the whole work, it is clear that every serious chemistry library will have to acquire this set .... Many transformations that one would like to be familiar with are now presented in convenient and completely up-to-date fashion. **Comprehensive Organic Chemistry** *will be an all but essential companion in synthetic explorations."*

R.U. LEMIEUX, FRS, Edmonton, reviewing Volume 4 (Heterocyclic Compounds; edited by P.G. Sammes, London):
"This fine contribution well surveys the exceedingly complex and ramified field of heterocyclic chemistry while remaining pleasantly readable ... It will undoubtedly find extensive use in both industrial and academic libraries. Consultants and research chemists should consider it for office usage – the retrieval in a coherent fashion of a wide range of important factual knowledge has been made reliably convenient."

W.S. JOHNSON Stanford, reviewing Volume 5 (Biological Compounds; edited by E. Haslam, Sheffield):
"To a synthetic organic chemist the chapters are not only comprehensible but interesting and highly informative .... This is a first-class treatment of the subject .... Haslam and his colleagues are to be congratulated for producing such a magnificent segment of the Barton-Ollis magnum opus which indeed represents a major contribution to scholars of organic chemistry."

J.E. BALDWIN, Oxford, is reviewing Volume 6 (Author, Formula, Subject, Reagent, Reaction Indexes; edited by C.J. Drayton, Oxford) and his review will be available shortly.

Copies of the full text of all the reviews, together with a brochure describing the work, may be obtained from the publisher on request.

Six Volume Set (only supplied in sets). To be published during the first quarter of 1979.
Price US$1250 £625 ISBN 0 08 021319 7 Approximately 8,000 pages.

Raven Press

JOURNAL OF CARDIOVASCULAR PHARMACOLOGY

Editors-in-Chief:
Jan Koch-Weser and William Pettinger

An international, multidisciplinary journal devoted to furthering the exchange of new information on cardiovascular pharmacology.

Published bimonthly beginning January 1979.
Volume 1: $48.00 U.S.A.; $56.00 Elsewhere

SLEEP

Editors-in-Chief:
William C. Dement and Christian Guilleminault

Sponsored by the three international societies covering the field of sleep—Association for the Psychophysiological Study of Sleep, European Society for Sleep Research, and the Association of Sleep Disorders Centers—this new journal will provide broad international coverage of sleep and sleep-wake research.

Published quarterly. **Personal subscription rates; $45.00**
Institutional subscription rates: U.S. $50.00; Elsewhere $60.00

THERAPEUTIC DRUG MONITORING

Editor-in-Chief: **C. E. Pippenger**

A new journal dedicated to the analytical and clinical aspects of therapeutic drug monitoring.

Published quarterly beginning in March, 1979.
Personal subscription rates: U.S.A. $40.00; Elsewhere $45.00
Institutional subscription rates: U.S.A. $50.00; Elsewhere $55.00

TRACER KINETIC METHODS IN MEDICAL PHYSIOLOGY

Niels A. Lassen and William Perl

This book provides a concise introduction to the mathematical treatment of tracers as used in medical and physiological research. Emphasis is placed on non-compartmental ("black-box") analysis, but the compartmental approach is also discussed, and the formal similarities are pointed out. The material presented is essential for all research workers in physiology.

226 pages (1979) $28.60

ORGANELLE HEREDITY

Nicholas W. Gillham

This text reviews what is known to date about the genetic material and protein synthesizing systems of chloroplasts and mitochondria. Also discussed are the roles played by organellar and nuclear genomes and cytoplasmic and organellar protein synthesizing systems in the biogenesis of these organelles.

636 pages, 7 x 10 inches (1978) $64.35

PATHOBIOLOGY ANNUAL 1978

Editor: **Harry L. Ioachim**

The latest volume in the prestigious PATHOBIOLOGY ANNUAL series brings together review articles on a broad variety of topics in pathology, each prepared by an expert in the field. Contributors: I. J. Russell and T. B. Tomasi; F. W. Quimby and R. S. Schwartz; G. L. Logue and R. J. Kurlander: H. Engelberg; J. A. Carney, G. W. Sizemore, and A. Hayles; K. M. Laurence and P. J. Gregory; D. F. H. Wallach; M. G. Lewis, T. M. Phillips and G. Rowden; J. G. Sinkovics; G. J. Stanton, H. M. Johnson, and S. Baron; S. Honig, S. Hoffstein, and G. Weissmann; A. Taranta; B. MacKay and B. M. Osborne; W. D. Bloomer and S. J. Adelstein.

450 pages (1978) $46.80

PLATELETS— A Multidisciplinary Approach

Editors: **Giovanni de Gaetano and Silvio Garattini**

This book presents a comprehensive and balanced overview of the multifaceted function of platelets. Papers are presented in the following subject categories: Platelets, Endothelium, Smooth Muscle Cells; Platelets and Inflammation; Platelets and Immunological Reactions; Platelets and Synaptosomes; and Platelets and Tumor Cells.

504 pages (1978) $46.80

OVARIAN FOLLICULAR DEVELOPMENT AND FUNCTION

Editors: **A. Rees Midgley, Jr. and William A. Sadler**

Sponsored by the Center for Population Research of the National Institute of Child Health and Human Development, U.S.A.

This volume is concerned with processes such as hormonally and nonhormonally controlled progressive functional and morphologic differentiation of thecal cells, granulosa cells, and oocytes; exogenous and endogenous hormonal regulation of receptors for protein and steroid hormones; and the eventual death through atresia or rescue by ovulation and luteinization.

310 pages (1978) $32.50

INTERNATIONAL CONFERENCE ON ATHEROSCLEROSIS Milan, November 1977

Editors:
Giorgio Weber, Lars A. Carlson, Rodolfo Paoletti and Cesare R. Sirtori

This comprehensive review of atherosclerosis provides a wealth of new, up-to-date data from a broad variety of clinical and basic studies.

800 pages (1978) $74.50

Circle No. 38 on Reader Enquiry Card.

that variation could be selectively neutral cannot be settled in the biochemistry laboratory.

Several essays touch on aspects of the relationship of Darwinism to human society and politics. There is much humane good sense here and I agree with most of it. Although 'sociobiology' is inspiring excellent research, Gould is right that it has also lead to some second-rate bandwagoneering. "But was there ever dog that praised his fleas?" asked Yeats. Perhaps a dog may be held responsible for the fleas that he sheds, but only to a small extent. At the AAAS meeting in Washington this year, Gould and I witnessed an organised attack on his most distinguished Harvard colleague. Gould well deserved his ovation for the apt Lenin quote with which he disowned the rabble. But as he watched those pathetic fleas ineffectually hopping around the stage chanting, of all things, "genocide", did he wonder with a little itch of conscience on which dog they had been sucking?

The Epilogue is forward-looking, and whets our appetite for the Volume 2 which I earnestly hope will be forthcoming. One theme which I know Gould has already carried further in his *Natural History* column is his dislike for "the ultimate atomism" of regarding organisms as "temporary receptacles . . . no more than instruments that genes use to make more genes like themselves" (p269). In describing this as "metaphorical nonsense", Gould underestimates the sophistication of the idea, first cogently expressed in its modern form by George C. Williams (*Adaptation and Natural Selection*, Princeton University Press, 1966 pages 22–25 and 56–57). The dispute is largely semantic. Inclusive fitness is defined in such a way that to say "the individual works so as to maximise its inclusive fitness" is equivalent to saying "the genes work so as to maximise their survival". The two forms are each valuable for different purposes. Both contain an element of personification; it is dangerously easier to personify organisms than to personify genes. The gene selection idea is not naïvely atomistic, as it recognises that genes are selected for their capacity to interact productively with the other genes with which they are most likely to share 'receptacles'; this means the other genes of the gene pool, and the gene pool may therefore come to resemble a "homeostatically buffered system" tending to return to (one of) its evolutionarily stable state(s). Irrevocable determination by genes is no part of the idea, nor is anything remotely approaching a "one gene one trait" mapping from genotype to phenotype. In any case it has nothing to do with "supreme confidence in universal adapttion" (p269), which is as likely to be found among devotees of "individual selection" or "species selection".

"I will rejoice in the multifariousness of nature and leave the chimera of certainty to politicians and preachers" (p271): a resounding conclusion to a stimulating book—the work of a free and imaginative scientific mind. The final, sad paradox is this. How can a mind capable of such rejoicing, open enough to contemplate the shifting splendour of three thousand million years, moved by the ancient poetry written in the rocks, how can such a mind not be bored by the drivelling ephemera of juvenile pamphleteers and the cold preaching of spiteful old hardliners? No doubt they are right that science is not politically neutral. But if, to them, that is the most important thing about science, just think what they are missing! Stephen Gould is well qualified, and strategically placed, to strip away even those dark blinkers and dazzle those poor unpractised eyes.

Richard Dawkins is Lecturer in Zoology at the University of Oxford, UK.

Evolutionary advantages of sex

Alan Robertson

Evolution of Sex. By John Maynard Smith, Pp.222. (Cambridge University Press: Cambridge and London, 1978.) Hardback £9.50; paperback £2.95.

"WHAT song the syrens sang or what name Achilles assumed when he hid himself among women, though puzzling questions, are not beyond all conjecture", and so it is with the evolution of sex. Maynard Smith takes up again points which were first discussed by Darwin and, often with tantalising brevity, in Fisher's classical book of 1930.

Maynard Smith himself added a most important point to the argument in 1971 that in sexual species there is an immediate selective advantage for a gene which would allow females to reproduce parthenogenetically. In a sexual population of fixed size, each individual has on the average two progeny in the next generation and each gene contributes on average one copy. Suppose a mutant occurs which, without reducing the numbers or the vigour of the progeny of a female allows her to reproduce parthenogenetically. She would still contribute two progeny but all their genes would come from her so that the new mutant would be represented on average by two copies in the next generation. The mutation would then spread rapidly through the population.

Thus, parthenogenesis passes the first test to be applied to any potential evolutionary change in a species—will the genes which favour it have in consequence a selective advantage. Such mutants are clearly possible. *Daphnia*, for instance, has adopted a strategy of cyclical parthenogenesis, breeding parthenogenetically in summer and sexually as winter approaches. A strain of turkeys is known in which a proportion of unfertilised eggs hatch—not very usefully in this case because all such progeny are male.

But there are further tests. Will species which have adopted this strategy be able to compete against their parental sexual species if the environment suddenly changes (for which the genetic variation in the species at any time is important) or when the environment is slowly changing over thousands or millions of generations, so that the species depends for successful change on its ability to accumulate new useful mutations, and also to get rid of the harmful ones. These are properties of the species as a whole rather than of its component individuals, so that competition is between populations—'group selection'.

A new and successful parthenogenetic species, having already passed the first test in its present environment will be less likely to pass the second two tests, as Muller showed. It will clearly be more genetically uniform at any time. The majority of new mutants will be harmful and the species will be less able to tolerate them than will a sexual species. This is Muller's famous "ratchet mechanism". He showed that asexual populations below a certain critical size, depend on the overall mutation rate to harmful genes and their average selective disadvantage, will decline in fitness, essentially because of continued chance of loss of the fittest genotype.

Muller also showed that a sexual population is very much more efficient in accumulating new advantageous mutants, at least in situations in which many such selective substitutions are occurring at the same time. In an asexual species, the only way that two advantageous mutants can be combined in the same clone is by mutation in that clone, whereas in a sexual species recombination is possible of mutations which originally occurred in different individuals. Muller presents these two arguments separately but I suspect that, as Felsenstein has pointed out, they really are aspects of the same process. Thus, we have two ways in which group selection will in the long term favour sexual compared with parthenogenetic species.

Maynard Smith's approach is to present first the theoretical aspects of questions and second to examine the available evidence in both plants and animals. He concludes that, though group extinction must play an important part in maintaining sexual reproduction, there must also be some short term advantages for sex.

It may not have escaped the reader that all the long term advantages of sex come from the independent assortment of chromosomes and that they therefore apply equally well to the maintenance of recombination. There is good evidence that the amount of crossing over on a given region can be altered by selection so that the raw material for natural selection is there. Theory would suggest that in a large population in a uniform environment, natural selection would in the short term favour a reduction in crossing-over. This requires epistatic interactions affecting fitness between genes at loci fairly close together on the chromosome. The arguments about the long term effects are the same as I have indicated for sex itself—indeed as initially presented the arguments referred to recombination rather than to sex.

Are there any short term advantages for recombination? Two are presented. The first, due to Maynard Smith himself, is in terms of competition between sibs. He shows that, if the environment varies widely from year to year and is described by several different variables, an individual of a given genotype in whose progeny there is segregation has a higher chance of producing successful offspring than one which does not. This he confirms in a model with five environmental features and five loci, one locus controlling adaptation to one feature of the environment. He finds clear selective advantage for higher recombination. The model, however, turns out to be not very robust to changes in the assumptions.

There is an alternative explanation, presented in a way that I found very obscure, even though I am an author of what is said to be the key paper. After much struggle, I arrived at an understanding as follows. Muller showed that, in the long term, a sexual species is better at accumulating advantageous new mutations and getting rid of bad ones. With no recombination, two useful mutations which have occurred in different individuals cannot be combined. Looking at the whole population, there is then a complete absence of gametes containing both. Felsenstein showed that, in one special case, Muller's argument could be extended to short term selection—gametes which had arisen by recombination would be fitter than those which had not.

Our paper dealt with selection in finite populations, and we showed that, if two advantageous linked mutants are under selection at the same time, they tend to block each other's progress, because, under the joint action of selection and random sampling, there is in such populations a shortage of gametes containing both mutations. Increased recombination then speeds up selection. But Muller says nothing about population size. On reflection, a critical part of his argument concerns the occurrence of new mutants as units—the total number of copies of any mutant in the population is certainly finite at critical stages. So perhaps our statement contains Muller's as a special case. Felsenstein was able to confirm by simulation that recombination would be selected for in finite populations in which new mutants, either advantageous or harmful, are occurring. I should say that I remain a little uneasy that such a major problem, the evolutionary implications of recombination, turns out to depend on such a 'second-order' mechanism.

Using the same general approach, the final third of the book deals with a series of secondary but related problems, such as the evolution of hermaphroditism, the avoidance of inbreeding, the evolution of anisogamy and the sex-ratio, and finally, thrown in for good measure, a discussion of optimal mutation rates.

I found the book stimulating in that it took me down many paths that I am not used to treading. It contains a fair amount of mathematics, which is almost all of the 'nuts and bolts' kind. But I did find it difficult. There could of course be three reasons for this—the author, the nature of the material, and finally the reviewer. I must say that I was a little taken aback when, having completely failed to penetrate a paragraph in one of the papers referred to, the authors then proceeded; "but the argument cannot really be this simple." ☐

Alan Robertson is Professor in the Department of Genetics at the University of Edinburgh, UK.

Shaking off the magic

P. B. Medawar

Magic, Science and Civilization. By Jacob Bronowski Pp.104. (Columbia University Press: New York, 1978.) $8.70.

BRONOWSKI believes that a radical and irreversible complex of changes in the character of civilised life took place between 1500 and 1700: that which followed the eruption *(sic)* of science into western civilisation. It is characteristic of the rather lazy and flabby character of this book that although he clearly does not mean it he refers to the complex of changes as a 'step' and likens it to a mutation. The "prime contemporary issue" is "the place of science in the total field of knowledge and that of human values as we have to reformulate them in this century".

Bronowski believes that round about 1600 (give or take a century) it became possible for the first time to propound a unitary theory of the world: "to see the world as a whole and from a single core or type of explanation". He mentions grave and well recognised objections to this view, without in my opinion, countering them.

Bronowski is rather good on magic, of which his definition is admirably simple: "It is the view that there is a logic of everyday life, but there is also a logic of another world. Science is distinguished from magical views by the fact that it refuses to acknowledge a division between two kinds of logic . . . There is only one logic; it works the same way in all forms of conduct and it is not carried out by any kind of formula . . .".

Alchemical notions had a profound influence on the development of chemistry and chemical technology and in comparatively recent years it has become clear from the research of Frances Yates, Paolo Rossi and Charles Webster that magical, supernatural and literally scriptural notions played a most important part in the thought of many of those whom we think of as pioneers and champions of modern science; in particular one thinks of Frances Yates's discernment of Rosicrucian and hermetic influences in, for example, the writing of Francis Bacon and his contemporaries here and abroad. Dr Joseph Glanvill, FRS, for example, was an ardent believer in witchcraft and at the same time a champion of the Royal Society and all it stood for. This division of mind must have been most unsettling: it is no wonder that a *Tempest* raged in Prospero's heart.

Modern science has shaken off magic but Bronowski is very clearly

An Historical Geography of England and Wales

edited by R. A. Dodgshon and R. A. Butlin

October 1978, paperback edition: xx + 450pp., £6.80/$14.00 0.12.219252.4
hardback edition: xx + 450pp., £14.80/$30.65 0.12.219250.8

During the last decade, historical geography has undergone important changes in both method and content, which greatly enhance its contribution to geographical studies. As it is now an integral part of the geography syllabus in many universities and colleges, there is an urgent need for a basic foundation text for undergraduates which incorporates these changes. This multi-authored, single-volume textbook will cater for just such a need. It reflects the important developments which have taken place in the discipline, not only in terms of ideas and understanding but in its original style of approach — it is perhaps the first to concentrate on an interpretative and explanatory angle as regards spatial patterning.

Seeing and Hearing and Space and Time

N. O'Connor and B. Hermelin

November/December 1978, viii + 158pp., £6.80/$14.00 0.12.524150.X

This book discusses the interrelationship between perceptual and cognitive processes, describing recent experimental work carried out by the authors with sensorily and cognitively impaired children. It reports and compares the coding strategies of blind, deaf, autistic, subnormal and normal children presented with different tasks, with the underlying hypothesis that sensory deficits will affect cognition, and cognitive impairment will in turn influence perceptual organization. The study groups were chosen to contain children of different intellectual attainment as well as different diagnoses, so that the question-begging explanation of cognitive deficit in terms of intelligence might be avoided and the components of the deficit properly analysed.

Reversibility of Female Sterilization

edited by Ivo Brosens and Robert Winston

November/ December 1978, x + 194pp., £7.50/$15.50 0.12.136080.6

Sterilization has become the most extensively used method of contraception, and at the same time the demand for reversal of sterilization has also increased. In view of this increasing demand, a number of leading specialists in the field were invited to discuss different aspects of potential reversibility of female sterilization at the first international symposium on the subject, held in Leuven, Belgium, in June 1977. This book comprises both the papers presented and the discussions held at the symposium. Although dealing mainly with technical aspects of reversal, the papers also include discussions on the scientific background to fallopian tube function (physiology, pathology and ultrastructure), different methods of sterilization with particular reference to their reversibility, and psychological and sociological aspects of reversal and the demand for it. *Published in New York by Grune & Stratton (ISBN 0.8089.1150.3)*

Rice in Africa

edited by I. W. Buddenhagen and G. Persley

December 1978/January 1979, xvi + 356pp., £12.50/$25.75 0.12.139350.X

Rice is traditionally thought of as an Asian crop and indeed a large proportion of the world's rice is grown there. However, certain African countries also have a long history of rice production and its cultivation is increasingly being introduced into others. It is important therefore that research and development specific to Africa is co-ordinated and encouraged if production is to be improved and best use is made of resources. To help stimulate communication in this area a conference was organised by the Institute of Tropical Agriculture in collaboration with the International Rice Research Institute, the Institut de Recherches Agronomiques Tropicales, and the West African Rice Development Association. This volume is the result of the conference.

New Trends in Bio-Inorganic Chemistry

edited by R. J. P. Williams and J. R. R. F. da Silva

December 1978/January 1979, x + 490pp., £12.50/$25.75 0.12.755050.X

This book concentrates on aspects of inorganic chemistry and biology which have often been overlooked. In the past, the main stress in bio-inorganic chemistry has been on metals such as iron, copper and magnesium. Here, by contrast, the overall objective is to indicate to the reader that a much larger number of inorganic elements are involved in bio-inorganic chemistry. Consequently, one major emphasis is on the biological roles of elements such as silicon and phosphorus. Undergraduates and graduates in biochemistry and inorganic chemistry will find this a stimulating approach to the subject and a valuable reference work. The book will also be useful to students of medicine who have an interest in trace elements and mineral metabolism.

Relativistic Quantum Fields

C. Nash

November/December 1978, x + 224pp., £15.00/$31.00 0.12.514350.8

In the last ten years there have been a number of attempts to make progress in various problems in quantum field theory. This has resulted in the creation of several new techniques which are now important for a research worker doing calculations in field theory. Among these techniques are the short distance expansion of Wilson, the dimensional regularization method, and the renormalization group methods. This book is an attempt to present these techniques in a form comprehensible to postgraduate students in their first and second years of research.

Methods in Microbiology

Volume 11

edited by T. Bergan and J. R. Norris

December 1978/January 1979, xvi + 314pp, £16.00/$33.15 0.12.521511.8

Interest in the factors controlling the spread of pathogenic bacteria in both human and animal populations has led, in recent years, to the development of various techniques for the characterization of isolates from epidemics. These take many forms. Biochemical tests, serological analysis, phage and bacteriocin typing are particularly important. Volumes 10-13 of ***Methods in Microbiology*** collect together, for the first time, the methods used in identifying all major human and animal pathogenic bacteria of epidemiological importance. The attention of practical detail will enable the methods to be followed in the laboratory, and it is hoped that this will lead to increased uniformity of method around the world.

Advances in Physical Organic Chemistry

Volume 16

edited by V. Gold and D. Bethell

December 1978/January 1979, viii + 274pp., £16.80/$34.75 0.12.033516.6

This is a well-established series for the publication of authoritative reviews on the methods and results of the application of quantitative physical and mathematical methods to organic chemistry.

Contents

John H. Ridd: Diffusion control and pre-association in nitrosation, nitration and halogenation. **John M. Tedder and John C. Walton:** Directive effects in gas-phase radical addition reactions. **John Albery and Maurice M. Kreevoy:** Methyl transfer reactions. **John O. Williams:** Electrical conduction in organic solids. **Stefan Berger:** Nuclear magnetic relaxation: recent problems and progress. Author index. Cumulative index of authors. Cumulative index of titles.

Rational Quadratic Forms

J. W. S. Cassels

November/December 1978, xvi + 414pp., £17.50/$36.25 0.12.163260.1

This monograph presents the main themes of the theory of quadratic forms at a level that can be appreciated by a wide variety of readers. The first half of the book develops the classical theory of rational and integral equivalence for quadratic forms with rational or rational integral coefficients. Full use is made of the insight and clarity provided by the use of p-adic numbers and of Witt's theory of quadratic spaces. The second half contains treatments of spinor genera, of reduction theory and automorphs, and of the composition of binary forms.

Proceedings of the Serono Symposia No. 14

Recent Progress in Andrology

edited by A. Fabbrini and E. Steinberger

December 1978/January 1979, xiv + 506pp., £17.60/$36.50 0.12.24.247350.7

Andrology is a relatively new discipline which has developed from inter-relationships between disciplines once regarded as isolated from each other. The endocrinologist, urologist, psychologist, neurologist, seminologist, paediatrician, geneticist, and many other specialists realised that their specialised knowledge converged in the field of clinical and experimental physiology and pathophysiology of the male. One of the first symposia to be organised around this multidisciplinary concept was held in L'Aquila in April 1977, the proceedings of which are presented in this volume. It covers all aspects of andrology including neuroendocrinology, testicular pathology and physiology, and antifertility agents and therapy.

Chemical Oceanography

2nd Edition Volume 7

edited by J. P. Riley and R. Chester

November 1978/January 1979, xvi + 508pp., £19.60/$40.50. 0.12.588607.1

Reviews of the First Edition "*. . . a most comprehensive review of the subject, and a work of real significance to the advanced student and research worker, and of interest to chemists, biologists and geologists in associated fields.*"
Chemistry in Britain.

Contents

E. J. W. Jones: Sea-floor spreading and the evolution of the ocean basins. **Ted C. Moore, Jr. and G. Ross Heath:** Sea-floor sampling techniques. **William M. Sackett:** Suspended matter in sea-water. **Walter W. Berg, Jr. and John W. Winchester:** Aerosol chemistry of the marine atmosphere. **Bernd R. T. Simoneit:** The organic chemistry of marine sediments. **Karl K. Turekian and J. Kirk Cochran:** Determination of marine chronologies using natural radionuclides. **S. R. Aston:** Estuarine chemistry. **L. D. Mee:** Coastal lagoons.

Advances in Parasitology

Volume 16

edited by W. H. R. Lumsden (Senior editor) and J. R. Baker

December 1978/January 1979, xii + 376 pp., £18.80/$38.75 0.12.031716.8

This latest volume, the first compiled by the new editors, continues the series along the same lines as under the editorship of the late Professor Dawes. In the past, the series has been widely recognised as a leading publication in the field, and has gained a high reputation for its in-depth and original reviews on a variety of subjects within the ambit of parasitology. The scope of future volumes will remain much the same as in the past, with the addition of some more medically orientated subjects, reflecting the bias of the new editors.

Proceedings of the Serono Symposia No. 18

The Endocrine Function of the Human Adrenal Cortex

edited by V. H. T. James, M. Serio, G. Guisti and L. Martini

December 1978/January 1979, x + 628pp., £19.50/$40.35 0.12.380160.5

This book is a record of the proceedings of a symposium held in Florence in October 1977. The meeting brought together a selection of speakers, many of whom have made important and fundamental contributions to the understanding of adrenal cortical functionings in recent years. This volume presents both a comprehensive review and details of current research on the many aspects of the functioning of the adrenal cortex for all those interested in human endocrinology.

Bioluminescence in Action

edited by P. J. Herring

November/December 1978, xxvi + 570 pp., £25.00/$51.75 0.12.342750.9.

The study of bioluminescence, the emission of light by living organisms, is not only rewarding in its own right but it has also provided invaluable tools and concepts in other areas of research as diverse as neurophysiology, space research and biological kinetics. *Bioluminescence in Action* provides a review of all aspects of bioluminescence, a phenomenon whose visible expression covers the gamut from bacteria to beetles and fungi to fishes. The individual chapters are written by specialists in particular aspects of the subject, each of whom has contributed substantially to its development in recent years.

Mining Geostatistics

A. G. Journel and C. J. Huijbregts

December 1978/January 1979, x + 600pp., £32.00/$66.25 0.12.391050.1

"Geostatistics is the application of the formalism of random functions to the reconnaissance and estimation of natural phenomena." With this definition, G. Matheron introduced the term *geostatistics* in 1962 to describe a new approach to certain problems in geology and mining. This approach encompasses the notion of the contradictory 'structure' and 'randomness' characteristic of, for instance, distribution of ore grades within a deposit: it provides a coherent and efficient set of probabilistic techniques, which are available to the geologist, mining engineer or metallurgist, and which require for their understanding only the most modest acquaintance with mathematical formalism. This book is the first manual and reference work on the subject.

Photographic Techniques in Scientific Research

Volume 3

edited by A. A. Newman

December 1978/January 1979, xii + 392 pp., £35.00/$72.50 0.12.517963.4

The third volume in an acclaimed series, this book continues the aim of the series in describing photographic techniques useful to various sectors of the scientific world. Increasingly, photography is being used by scientists either as an accurate means of recording and measuring data or as a sensitive instrument for clear observation. Thus it is essential for scientists to have easy access to the advances in method and equipment which are constantly being made. Six highly-qualified specialists have provided papers on different applications of photography to scientific research. Yet readers need not confine themselves to the chapter on their specific field of interest since, by adapting the techniques described in other sections to their own particular discipline, they can discover much that will be of use to them.

Round Table Discussion on Gentamicin and Tobramycin

edited by R. Richardson

November/December 1978, viii + 64pp., £5.00/$10.25 0.12.587780.3 (Academic Press) 0.8089.1149.X (Grune & Stratton)

This discussion, sponsored by Schering Corporation, held in London, 13 February 1978, is based on presentations made at the Tenth International Congress of Chemotherapy in Zurich. A worldwide group of experts in aminoglycoside therapy who were present at Zurich discuss their data and their interpretation of these findings.

Contents

Introduction. **Part I:** Microbiology. Comparative in vitro activity of gentamicin and tobramycin. **Part II:** Toxicology. Ototoxicity. Nephrotoxicity of gentamicin and tobramycin in animal models. **Part III:** Clinical. Personal experience of gentamicin ototoxicity. The frequency of ototoxicity — a review of the literature. Personal experience with the aminoglycosides. Summary.

Published jointly by The Royal Society of Medicine, Academic Press (London) and Grune & Stratton (New York).

Special Publications of the Society for General Microbiology

Coryneform Bacteria

edited by I. J. Bousfield and A. G. Callely

October/November 1978, x + 316pp., £9.20/$19.00 0.12.119650.X

The classification and identification of the coryneform bacteria, a widely distributed and important group of organisms, have long been difficult and confused. In this book, the first in a new series of publications arranged by the Society for General Microbiology, the authors aim to show how the application of modern taxonomic methods is rapidly changing standard views on the systematics of these bacteria, and how a reliable taxonomy seems to be emerging at last.

Huckel Theory for Organic Chemists

C. A. Coulson, B. O'Leary and R. B. Mallion

November/December 1978, xvi + 182pp., £9.50/$19.65 0.12.193250.8

The late Professor Coulson virtually created Hückel Theory in its present form; future generations are therefore extremely fortunate that Drs. O'Leary and Mallion, who compiled this book, not only possessed his notes but also tape-recordings of his lectures to third-year undergraduate chemists. A gifted teacher who had taught most of the present leaders in the field of theoretical chemistry throughout the world, Professor Coulson had considered putting his lectures into book form. After his death in 1974, two of his former students and friends — Dr. Brian O'Leary and Dr. Roger Mallion — decided to carry out this task on his behalf. The result is a fascinating work which describes a field of chemistry which will always be linked with the name of C. A. Coulson.

FEMS Symposium No.5

Antibiotics and Other Secondary Metabolites

Biosynthesis and Production

edited by R. Hütter, T. Leisinger, J. Nüesch and W. Wehrli

November/December 1978, xii + 256pp., £14.40/$29.75 0.12.363250.1

Contents

The search for new secondary metabolites. Manipulation of gene expression in the development of antibiotic production. Process design and control in antibiotic fermentations. Microbial transformations — type reactions. Microbial transformations — some applications in natural product chemistry. Formation of tetracycline antibiotics. Biosynthesis of macrolide antibiotics. Rifamycin biogenesis. Developments in the chemistry and biochemistry of β-lactam antibiotics. Genetics in the development of the penicillin process. Genetics and biochemistry of cephalosporin biosynthesis. Ergot alkaloids — recent advances in chemistry and biochemistry. Genetic aspects of the formation of ergot alkaloids. Formation of ergotoxine alkaloids by fermentation and attempts to control their biosynthesis. Subject index.

Physiological Aspects of Anaesthetics and Inert Gases

A. G. Macdonald and K. T. Wann

November/December 1978, xii + 306pp., £17.50/$36.25 0.12.464150.4

Anaesthetics and inert gases affect almost every biological function, causing important changes in the physiological state of the body. This book discusses these various effects, and, in addition, provides an introduction to the scientific basis of anaesthetic action, as well as an account of the ways in which anaesthetics are used as probes in physiolcgical research. The subject has been approached by considering a wide range of physiological phenomena and discussing the effects of anaesthetics and inert gases on each of these, bringing such effects into scientific perspective.

Society for Applied Bacteriology Symposium Series No. 7

Streptococci

edited by F. A. Skinner and L. B. Quesnel

November/December 1978, xiv +416pp., £18.00/$37.25 0.12.648035.4

The genus *Streptococcus* comprises organisms which have a wide ranging impact on man and animals. This volume, which contains the papers given at the 1977 Society for Applied Bacteriology Symposium, provides a broad synopsis of the various facets of this important genus. It gives a description of the organisms themselves, their biochemical potential and the position they hold in the classification of bacteria. Many of the members are causative agents of disease, and their effects are considered in detail from the viewpoints of human medicine, dentistry and veterinary science. The streptococci also include organisms of enormous economic importance to man, such as those used in the dairy industry for the production of cheese and fermented milk products. Other species are of use in evaluating water and food pollution and some have a significant role in the digestive processes of ruminant animals. All these and other aspects of the streptococci are reviewed in this volume.

Strategies of Information Processing

edited by Geoffrey Underwood

October/November 1978, x + 456pp., £20.00/$41.40 0.12.708950.0

This is one of the most important books on experimental psychology to appear since Neisser's *Cognitive Psychology* in 1967. It not only deals with recent empirical developments in the area of cognition, but also sets out a theoretical framework in which these developments can be seen to be working. In essence, this is the distinction between cognitive structure and the strategies used to manipulate this structure around our environmental problems that are set. The notion of strategies of information processing is a powerful concept, and is used in the book to indicate how information processing theory can account for the variety and richness of an individual's behaviour whilst carrying out different tasks.

Biochemical Aspects of Plant and Animal Coevolution

edited by J. B. Harborne

October/November 1978, xviii + 436pp., £24.60/$50.90 0.12.324672.3

Our understanding of the significance of secondary plant constituents in plant and animal interactions has developed rapidly in recent years. So much so that it was considered timely to review the major developments since 1971, when the first meeting on this topic was held by the Phytochemical Society and published under the title "Phytochemical Ecology". This present volume is the result of the second meeting held in the University of Reading in 1977. Plant-insect interactions were among the first to be examined and still receive most attention. Among such studies discussed in this volume are the interactions between host plants and various insects — aphids, armyworms, bees, butterflies, grasshoppers, locusts and whiteflies.

Metal Alkoxides

D. C. Bradley, R. C. Mehrotra and D. P. Gaur

November/December 1978, viii + 412pp., £28.50/$58.00 0.12.124250.1

The metal alkoxides are a family of compounds exhibiting a wide range of physical and chemical properties. Much of the knowledge about these compounds has been obtained in the last 2-3 decades, and with the use of modern spectroscopic techniques and X-ray structural analysis, further advances are occurring rapidly. Although there have been several review articles on specific aspects of metal alkoxides, this book is the first comprehensive treatise on the subject and provides a perspective of the place of metal alkoxides in chemistry.

Biochemical Mechanisms of Liver Injury

edited by T. F. Slater

November/December 1978, approx. 850pp., £40.00/$82.75 0.12.649150.X

The book is primarily concerned with describing the variety of biochemical disturbances underlying a number of important liver injuries and diseases. Certain aspects in particular are emphasised, such as the role of metabolic activation of many hepatotoxins and hepatocarcinogens in the development of liver injury; the transient nature of such activated intermediates which makes rapid reaction studies necessary for their investigation; the importance of free radical reactions in the biochemical disturbances produced by these transient intermediates; and the multiplicity of protective mechanisms that may be applied. The book also includes some chapters dealing with the applications of relatively new techniques such as electron spin resonance, nuclear magnetic resonance.

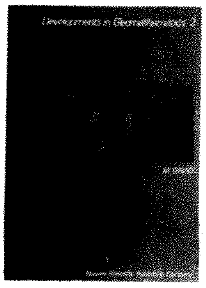
New from Elsevier



Geostatistical Ore Reserve Estimation

by MICHEL DAVID

Developments in Geomathematics, 2

Provides the reader with all the information necessary for implementing geostatistics in a mining company. Several computer programs are provided to solve the essential problems and it is explained how to actually generate a complete system for huge operations.

"... the first comprehensive textbook in English on the subject it certainly fills this need both for the student and the qualified mining engineer."
- World Mining

1977. 1st repr. 1978

Fluids in the Earth's Crust

Their Significance in Metamorphic, Tectonic and Chemical Transport Processes

by W. S. FYFE, N. J. PRICE *and* A. B. THOMPSON

Developments in Geochemistry, 1

Neither a traditional text on metamorphic petrology, nor a treatise on structural geology, this unique work transcends the conventional separation of these two fields by treating them in a unified way. The central theme is the role of fluids in tectonic, metamorphic and geochemical processes, and the text will undoubtedly find application and interest among a wide range of readers.

aware of the degree to which a predilection for the magical and mysterious persists amongst laymen in the cult of various forms of contemporary irrationalism.

I thought Bronowski's book not nearly as original, profound or illuminating as one might have hoped from a man of his learning and intelligence. It gives me the impression, too, of having been rather lazily written, as if it had all come too easily to him. ☐

Power of the scientific metaphor

M. J. Morgan

Programs of the Brain. By J. Z. Young. Pp.325 (Oxford University Press: Oxford, 1978.) £5.95.

THE conceptual problems of biological development are perhaps clarified, but made no easier of solution, by the notion that the genes encode, not so much characters in the old-fashioned sense, but rather programs or sets of instructions for development. Until this metaphor became available, the only alternative to a crude preformationist kind of innatism was a mysterious force such as Driesch's "entelechy", which would allow the developing organism to survive the vicissitudes of the environment and the embryologist's knife. The idea of the program for development is novel because it allows a complete determinism to coexist with flexibility in development. To give just one example, a vertebrate limb bud on the left side of the body can grow into a mirror image of its normal form if transplanted on to the right side of the body, because its developmental program does not specify which limb it should be, but rather how it should grow in relation to surrounding tissue. An apparently marvellous example of flexibility turns out to depend on rather an economical program.

The analogies between embryology and the empiricist–nativist controversy in psychology are very striking, as J. Z. Young makes clear in this admirable book. There was a great need for someone equally versed in biology and psychology to write a book such as *Programs of the Brain*, and Professor Young has succeeded in getting the essential logical points across to the non-specialist reader. There will be no excuse, after reading this book, for confusing the proposition that innate factors control psychological development with the preformationist concept of 'innate ideas'. Equally, it is made clear that 'learning' cannot be invoked in complete opposition to nativism, as learning itself is nothing but a program for acquiring certain kinds of knowledge. Stones, after all, learn nothing, and different animals learn quite different things. This reworking of the nativist–empiricist controversy has been commonplace in ethology for some year now, but it is useful to have it so clearly brought to the attention of the general reader.

Logical clarity alone, however, does not tell us how things work. And the unsatisfactory feature of this book, as J. Z. Young freely admits on several occasions, is that we really don't know how 'programs of the brain' work at all. The problem with a metaphor such as 'program' is that it gives an illusion of understanding, an illusion that gains powerful force from mere repetition. A previous generation of psychologists was excited by the telephone exchange model of the brain. The computer analogy is very probably an improvement, but as this book concludes with proper detachment, in the future ". . . perhaps a new form of laughter will also echo through the system, as the information comes up that in 1978 the best way the ancients had to describe these processes was to call them Programs of the Brain". One does therefore wonder what is to be gained by saying that there are programs for "loving and caring, fearing, hating and fighting, hearing, speaking and writing" (to mention but a few from the chapter headings). We are given very little clue as to how these programs work, and the mere verbal redescription smacks uncomfortably of the behaviourist's irritating habit of relabelling something like play as "ludic behaviour" and thinking that they had said something substantial.

One interesting hint J. Z. Young throws out is that brain programs for vision may depend crucially on topographical representation of the input. He suggests that our capacity for solving problems by visual imagery may depend on cortical maps of this sort. It would be interesting to have a further working out of this idea, which—understandably in a book of this scope—is not expressed in anything more than an allusive form. The idea seems to be that visual representation may consist at least in part of 'symbols', which in themselves have some features of the represented state of affairs,

rather than being mere arbitrary 'signs'. This useful distinction between signs and symbols, which J. Z. Young makes rather clearly at one point, is unfortunately blurred later on when he speaks of colours as 'symbols'. The more usual view is that colours are arbitrary signs for different wavelengths of light. When J. Muller gave the first systematic expression to the doctrine of specific nerve energies in 1838 (not 1848 as stated in this book) he was expressing the idea, well known to Hobbes and other philosophers, that the quality of a sensation depends on the nerve that is stimulated, rather than on some property of the stimulating agent. Young and Helmholtz later extended this to different nerve fibres, proposing that perceived colour depends on the nerve channel stimulated. This seems to make colour a purely arbitrary sign. But J. Z. Young is perhaps insisting on something more profound in calling colour a symbol. There would be no need for an animal to respond to a wavelength at all unless it were significant in some biological sense, and it could be that colour is a symbol of this significance, as the phenomenologists such as Merleau-Ponty have argued, instead of being an arbitrary sign of a wavelength.

As this book is written for the non-specialist it is worth noting with satisfaction that it has been produced by the Oxford University Press for only £5.95, complete with many excellent illustrations. This excuses certain oversights, such as a systematic disordering in the page references to the Bibliography, as if the latter had been added to at some stage without corresponding changes in the index. When *Programs of the Brain* goes into further editions, as it undoubtedly deserves, one hopes that this minor imperfection will be put right. □

M. J. Morgan is Professor and Head of the Department of Psychology at the University of Durham, UK.

Gloss on scientific practice

Stuart Sutherland

How We Know: An Exploration of the Scientific Process. By M. Goldstein and I. F. Goldstein. Pp.357. (Plenum: New York and London, 1978.) $17.94.

IT is a truism that the finished product of scientific endeavour—the successful theory—is very different from the halting steps by which it is usually reached. *How We Know* attempts to describe both the methods of discovery and the product: it is more successful at characterising the former than the latter.

Half the book is devoted to three illustrative case-histories—Snow's proof that cholera can be transmitted through drinking water, Rumford's experiments on heat, and the history of research into schizophrenia.

Snow is often credited with being the founder of epidemiology and although his work is well known, the story is worth retelling in somewhat more detail than usual. The final proof of his hypothesis was based on his discovery that one district in London was supplied by two separate water companies, one of which drew its water from a comparatively uncontaminated stretch of the Thames, the other from a region containing much of the sewage of London. Snow was able to show that although the houses supplied by the two companies were quite randomly distributed within the district, the death rate from cholera was ten times as high in the houses supplied by one company as in those supplied by the other. This finding was the culmination of much patient work. Snow already knew, for example, that doctors, who always washed after attending a patient, rarely caught cholera, whereas those "women of the working class" who laid out the bodies and made "the occasion one of eating and drinking" frequently did. Having formed the hypothesis that cholera was transmitted by swallowing "the ejections and dejections of cholera patients", Snow persisted with it in the face of some evidence that seemed incompatible. Not everyone who drank heavily contaminated water became ill: the same argument is still used by confirmed smokers as a disproof of the fact that smoking causes lung cancer.

Both the account of Snow and that of Rumford gain in interest by being told largely in their own measured and elegant prose: if only today's scientists had the talent and leisure to write like their predecessors, how much more pleasureable the pages of *Nature* would be. Like Snow, Rumford persisted in clinging to a hypothesis: he believed in the kinetic theory of heat at a time when the caloric theory—that heat is a substance—was widely accepted. He showed that within the limits of his apparatus heat had no weight and that when cannon muzzles are bored an indefinite quantity of heat could be produced by friction; he also discovered molecular diffusion, attributing it to the motion of molecules. But although his theory was correct, there were too many facts that at the time seemed more consistent with the caloric theory for it to be accepted: the rival theory gave a better account of such phenomena as latent heat and the transmission of heat by radiation across a vacuum. As Martin and Inge Goldstein note, the caloric theory, although wrong, itself led to many discoveries, including the laws governing heat capacity and the transmission of heat from one substance to another.

The authors' account of schizophrenia is perhaps the least interesting of their three case-histories: our knowledge of schizophrenia has been advanced by many different investigators and the story does not bear the imprint of a single mind in all its individuality. Moreover, as they acknowledge, they omit a great deal of the evidence that bears on the nature of schizophrenia so that some of the conclusions they record stand up rather better than is evident from their description. For example, they do not mention the World Health Organisation's massive study which established that both the prevalence of the illness (at least in its 'nuclear' form) and its symptoms show little variation across nine widely divergent cultures.

Although their case-histories make agreeable reading, the conclusions the authors draw from them are hardly new. Scientific discovery usually stems from the more or less systematic testing of hypotheses; luck may play a role; the investigator must be ready to take advantage of the chance observation that may prove significant; intuition plays a large part; the mechanisms underlying creativity are unconscious and ill understood; and stubborn persistence in a hypothesis in the face of apparently contradictory evidence can lead to major advances. They forebear to point out that persistence can also lead to disaster—any scientist knows of colleagues who spend dismal years following out an unprofitable hypothesis or approach: it is impossible either to know in advance whether persistence will be rewarded or to characterise the intuitions which enable the best scientists to judge when persistence is warranted and when it is not.

On the progress of science, the Goldsteins take a Kuhnian position, but like him they tend to overdramatise the nature of revolutionary changes in scientific paradigms. It is true that in some cases, such as Newtonian physics, the theory of evolution, or relativity theory, a single piece of work has made a great many seemingly disparate facts fit together and has at the same time produced a fundamentally new way of looking at things. But even in

The scientific, technical and medical division of Associated Book Publishers Ltd, 11 New Fetter Lane, London EC4P 4EE.

ANIMAL BEHAVIOUR IN THE LABORATORY

Behavioural tests and their interpretation illustrated mainly by psychopharmacology in the rat.

PAUL SILVERMAN

A first comprehensive guide to animal behaviour as an applied science. It includes practical details of all the main methods, including operant conditioning as well as older tests based on maze-learning, or conditioned reflexes as used in the Soviet Union. A special feature is its ethological analysis of exploratory and particularly social behaviour using methods developed as tests in large part by the author.

Written in a lively, accurate style, this book will be of interest to undergraduates studying life science courses involving animal behaviour and psychology; to postgraduates and industrial research workers in pharmacology and toxicology laboratories.

* NERVE MUSCLE INTERACTION

G. VRBOVÁ, R. JONES and
T. GORDON

An overall view of the development of nerve and muscle, their interdependence and the maintenance of their interaction in the mature animal. The development of highly specialized and differentiated skeletal muscle fibres from unspecialized cells is discussed, together with the dependence of this process on innervation. The value of various experimental approaches designed to investigate the maintenance of the muscle fibre membrane and the contractile mechanism is examined and their relevance to our understanding of neuromuscular disorders is considered.

* STOCHASTIC ABUNDANCE MODELS

With Emphasis on Biological Communities and Species Diversity

S. ENGEN

Mongraphs on Applied Probability and Statistics

Part 1 of this monograph considers the mathematical and statistical basis of stochastic abundance models and could be used by any scientist who has to deal with communities of elements which are sub-divided into a large number of mutually exclusive and exhaustive classes.

Part 2 is devoted to ecological applications. The practical interpretation of abundance models in ecology is discussed and methods for judging the goodness of fit are given.

1. **NEUROBIOLOGICAL THEORY OF PSYCHOLOGICAL PHENOMENA**

G.D. Wassermann

A refreshingly original look at the way in which the human nervous system could generate and represent both perceptual and cognitive phenomena as well as actions. Wassermann uses his theory to explain a considerable variety of phenomena, including a possible neural basis of memory, depth perception, aspects of Gestalt psychology, and possible representations of concepts and language.

£15.00 0 333 23792 7 Sept. 1978

2. **PHARMACOLOGY OF THE HYPOTHALAMUS**

Edited by B. Cox, I.D. Morris & A.H. Weston

There has been considerable research activity recently dealing with the hypothalamus and its surrounding areas, but there has been no review of the pharmacological implications of the work. This volume is designed to fill that gap. Among the topics covered by the internationally recognised group of contributors are the functional anatomy and endocrinology of the hypothalamus, its neurotransmitters and peptide hormones and the clinical evaluation of hypothalamic disease.

£12.95 0 333 22606 2 Oct. 1978

3. **ANIMAL MARKING: RECOGNITION OF ANIMALS IN RESEARCH**

Edited by Bernard Stonehouse

ANIMAL MARKING, the edited proceedings of an RSPCA-sponsored symposium, is the first publication to gather together such a vast collection of techniques and expertise on humane methods of marking animals for research. Current marking methods for animals ranging from molluscs to elephants are discussed by the 27 contributors.

£10.00 0 333 23584 3 November 1978

4. **ENERGY AND THE ENVIRONMENT: Democratic Decision Making**

Edited by J. Surrey, Christian Lenzer, C. Phipps and J. Vallebx

The outcome of a lively conference at the Council for Europe in Strasbourg, this book examines the challenges facing Europe over the next quarter-century arising from the complex and interrelated problems of energy and environment policy. The editors rigorously try to explain the varied expert viewpoints expressed at the conference and the interrelationship between the political and social aspects and the technological and economic aspects.

£5.95 0 333 25627 1 Dec. 1978

5. **INTRODUCTION TO PROBABILITY AND MEASURE**

K.R. Parthasarathy

This book gives a simultaneous introduction to probability theory and measure theory. It assumes an elementary knowledge of general topology and discusses such topics as properties of Borel maps, isomorphism theorem, Daniel–Kolmogorov consistency theorem, theory of integration and the weak convergence of probability measures.

£10.00 0 333 21855 8 Oct. 1978

6. **POLAR DIELECTRICS AND THEIR APPLICATIONS**

J.C. Burfoot & G.W. Taylor

Polar materials are of great scientific interest and economic importance. In this book the authors examine the preparation, properties, theory and applications of ferroelectric and non-ferroelectric, polar materials.

£20.00 0 333 17958 7 Feb. 1979

7. **ENDORPHINS IN MENTAL HEALTH RESEARCH**

Edited by Earl Usdin, W.E. Bunney, and Nathan S. Kline

This collection of papers provides an unparalleled account of the current state of research in this new field of neuroscience. The vital issues covered are bound to stimulate a renewed controversy and further research activity – both from those already directly involved and from those who feel that they cannot ignore the increasing relevance of endorphins to their own work.

about £20.00 0 333 24269 6 Feb. 1979

8. **GENERAL RELATIVITY AND COSMOLOGY**

Prof. J.V. Narlikar

The author analyses critically General Relativity as applied to cosmology and presents a thorough survey of current cosmological theories. Amongst the hypotheses which Narlikar examines in great detail is that which proposes two gravitational constants, viz., the Hadron constant, and the Einstein constant.

£9.95 0 333 24153 3 Feb. 1979

Statistical Treatment of Experimental Data

Physical Sciences Data 2

J. R. GREEN *and* D. MARGERISON, *University of Liverpool.*

"This is a book that should not only be read but used by all experimentalists". Journal of Molecular Structure

First published in 1977, this book met an unusually strong demand, which has led to early reprinting. The authors have taken the opportunity to make a number of minor revisions. The book is intended for researchers wishing to analyse experimental data using statistical methods. Consideration is given to a large number of practical topics which are often omitted from standard texts.

1st revised reprint Autumn 1978 x + 382 pages US $39.25/Dfl. 90.00 ISBN 0-444-41725-7

Evaluation and Optimization of Laboratory Methods and Analytical Procedures

A Survey of Statistical and Mathematical Techniques

Techniques and Instrumentation in Analytical Chemistry - Volume 1

D. L. MASSART, A. DIJKSTRA *and* L. KAUFMAN; *with contributions by S. Wold, B. Vandeginste and Y. Michotte.*

This book provides detailed treatment, in a single volume, of formal methods for optimization in analytical chemistry. All aspects of optimization are discussed, from the simple evaluation of procedures to the organization of laboratories or the selection of optimal complex analytical programmes. This work will be of practical value not only to those involved with optimization problems in analytical chemistry, but also to those in related fields such as clinical chemistry or specialized fields such as chromatography. It will also serve as a general introduction to the new field of Chemometrics.

Autumn 1978 xvi + 596 pages US $57.75/Dfl. 130.00 ISBN 0-444-41743-5

Instrumentation for High-Performance Liquid Chromatography

J. F. K. HUBER (Editor), *University of Vienna.*

Journal of Chromatography Library - Volume 13

A practical guide for all those involved in the application of column liquid chromatography, this book provides a valuable, up-to-date review of the large selection of instrumentation currently available. Special emphasis is given to discussion of the general principles of design which will remain relevant even if new technical solutions are found in the future. The final chapter comprises a useful compilation of commercially available chromatographs together with their specifications.

"This is a beautiful presentation of the nature of space and time and of general relativity as a human endeavour" — William Press, Harvard University

GENERAL RELATIVITY FROM A to B

Robert Geroch

Geroch explains the fundamental ideas of Einstein's theory in a non-technical style in this book. He shows why we need such a theory, what kinds of physical phenomena it encompasses, and what its applications and predictions are. He translates physical experiments into the language of space-time geometry, and the predicted outcome of those experiments back into physics.

A revolutionary new theory about the extraterrestrial origins of life

Lifecloud

The origin of life in the universe

FRED HOYLE & N. C. WICKRAMASINGHE

In one of the most important astronomy books to appear for many years, the authors' theory dramatically shatters the accepted idea that life started in the primeval soup here on Earth. They argue that a primitive biological system evolved in interstellar space and was carried to our planets, and probably others, by meteorites. The implications are momentous — *Lifecloud* marks a new era in our understanding of the universe. **£5.95**

A highly readable account of the amazing ways in which animals show unusual behaviour:

Just like an Animal

MAURICE BURTON

Are animals capable of intelligent actions? Do they respond to the suffering of others. Can a dog show sympathy or gratitude. Just some of the fascinating questions answered in Maurice Burton's important contribution to our understanding of animal emotions. Illustrated with 36 photographs and 19 line drawings. **£5.50**

DENT

Circle No. 50 on Reader Enquiry Card.

such instances many of the ideas were in the air at the time, and in other cases revolutions in ways of thought have occurred more insidiously. Pavlov and Sherrington, for example, had the fundamental insight that it was possible to investigate the nervous system by examining its input and output and inferring the intervening mechanisms, but much of Pavlov's own theorising was wrong and despite the importance of his research, Sherrington's *magum opus, The Integrative Action of the Nervous System* did not itself integrate many facts. Moreover, the Goldsteins place little emphasis on the importance of new techniques, the development of which often leads to fundamental new insights.

Their discussion of the finished product of science is inadequate. They point out that the Azande's beliefs about witchcraft are internally consistent and impossible to refute either by appeals to common sense or logic, and elsewhere they note the similarities but not the differences beween scientific and artistic endeavour. They raise but do not answer the question "Is what we have called the scientific method . . . a better, surer road to truth and understanding than any other?" Partly through Kuhn's influence, and partly perhaps through a loss of confidence in our own civilisation, it has become fashionable to lump science together with other systems of thought and to claim that it has no unique claim to objective truth: this tendency has surely gone too far.

Mystical systems do not enable us to control or to predict accurately events in the outside world though some may help us to control ourselves; most such systems could be as tenaciously held as they are if the world were very different from the way it is; science is not just one amongst many possible and equally valid ways of viewing the world. It attempts to construct models which fit the facts with the utmost precision, and which combine generality with economy. Works of art operate upon us obliquely, are often ambiguous and leave so much unstated that different people can project into them different significances. Scientific theories, on the other hand, attempt to state unequivocally all their underlying assumptions, to remove all ambiguity, and to arrive at a system that can only be understood and manipulated in one way.

Despite its failure to come to terms with the nature of the products of science, *How We Know* is an interesting, if slightly elementary, gloss on scientific practice. ☐

Stuart Sutherland is Professor of Experimental Psychology at the University of Sussex, UK.

Dynamic equilibrium of science

John Ziman

Science as a Human Endeavour. By G. F. Kneller. Pp.333. (Columbia University Press: New York, 1978.) $17.45.

SCIENCE used to seem simple. There were Laws of Nature to discover. There was a Scientific Method. Scientists were clever people, although aloof and uncultured. The marvellous new devices that benefited mankind came with dangerous new ideas that sapped the consolations of religion. Science was inhuman and incomprehensible; it was fortunately useful, even if it was unfortunately true.

To the more realistic studies of recent years, science has begun to seem more and more diverse, and more and more paradoxical. Its subject matter can vary from butterflies upon the wing to neutrinos trapped in a black hole. Methods of research range over techniques as diverse as electronic data-processing, opinion surveying, cinephotography and the playing of simulation games. An experiment may involve launching a space probe to Venus—or persuading a student of psychology that he is (perhaps?) near to electrocuting an innocent victim. A theory may be all algebra, or all words—and it may apply to the symmetry group of an elementary particle or to the elementary behaviour of a small human group. Scientists themselves vary from the speculatively divergent to the pedantically convergent, from sober realists to wild fantasists, from saints to sinners, from the fastest wits to the slowest bores, from high achievers to utter bunglers.

In the making of science there is the ever-present contrast between the solidity of established knowledge and the fluidity of conjectured novelty. In its applications, the incalculable benefit of a penicillin cannot be squared with the calculated horror of a napalm. Scientists belong to the most universal, transnational world community; at the same time, they are the most trusted servants of their warring governments. Scientific knowledge is as objective as we can make it; yet it is created out of the most subjective sweat of the individual human brow.

This diversity out to the limits of conceptual, technical, psychological, political and moral contradiction, characterises science as a human activity. It cannot be cramped into narrower formulae, such as "All science is quantitative", or "All science derives from technology", or "All science is revolutionary" or "All science must serve the State". It would be a profound error to recoil from the evident complexity into yet another over-simplified stereotype.

With this, I think, Dr Kneller would agree. His excellent chapter on "The Scientist as a Person" emphasises the historical diversity of personalities and styles of thought. But he has not faced up to the necessity of finding the unifying factors in this vast endeavour. There is more coherence than he discloses, in the philosophical analysis of competing research programmes, the sociological analysis of norms and invisible colleges, or the economic analysis of science policy. He has read about, and adequately summarises, these various manifestations of the contemporary study of science, but fails to capture the leviathan beneath the surface. This is a graver defect in a thoughtful and lucidly written book than the many minor errors of fact that would irritate a well informed reader.

The heart of the scientific enterprise is the dynamic bond between individual and collective forces. Personal attributes of curiosity, intelligence, creativity and ambition are cleverly harnessed by communal restraints of organised criticism, institutionalised competition and the kicks and halfpence of social esteem. The "search for order in nature", Popperian falsification, Kuhnian paradigms, referees and peer review, graduate education, and many other diverse and apparently contradictory features of science, fall into place around this tense and quivering bond. This is the secret of the "Scientific Method".

What comes out of this is a body of knowledge with a few general characteristics. To achieve an adequate degree of consensus, science must concentrate on the material, demonstrable, publicly shared aspects of the world. The product of long, deep and highly imaginative study may look as 'unreal' as quantum theory; but this is no more mystical or unpractical than the mechanism of an earthquake or the anatomy of a louse. Ultimately a scientific theory can only commend itself by its predictive power—by an evident coherence between a conceptual scheme and the results of deliberate action.

Because it has had to stand up openly to expert criticism, established scientific knowledge is reasonably free from wild fantasies and obvious inconsistencies. But the product of fallible human beings inevitably contains many minor mistakes, as well as grand misconceptions derived from the general opinions of the day. These deficiencies must be allowed for—yet they are incorrigible by reference to any principle that lies outside science. Scientific error can only be driven out by further science. Such progress may be much slower and more difficult than we would like—and in some cases may even prove illusory. Yet the process of self-correction is inherent in the method of science.

Scientific knowledge, being active rather than contemplative, is eminently applicable. Sophisticated technology may derive in large measure from science, and may provide the means and the motives for the investigation of particular questions. But neither the needs of practice, nor human aspiration, can determine the outcome in advance. Scientific knowledge is as objective and neutral as a frying pan or a sword: it is fit for such uses as those who possess it may desire, and for which it is appropriate, but neither can cook nor kill on its own account.

For all the philosophy and political sociology in the world, these maxims cannot be seriously controverted. But the scientific endeavour is questionable in several aspects that are scarcely mentioned by Dr Kneller. What is the potential scope of the scientific "method"? We feel sure that it cannot encompass ethical or aesthetic issues. When allowance has been made for the reflexive feedback of consciousness, can science provide reliable knowledge about human behaviour in general? Is the objective of a 'science of society' essentially self-contradictory—a bootstrap exercise in which one always ends up flat on ones back? This question is important, because every unjustifiable claim to scientific expertise in social affairs is a terrible danger to humanity.

Another serious question is whether the social system of science can stand the strain that is put upon it by modern society. The scientists of our day still live and work according to the principles of the academic science of the past. But will the dynamic equilibrium between individual and collective forces still be possible in the industrialised and bureaucratised technical organisations of present-day research? The fundamental contradiction of contemporary science is between the technocratic impulse to turn science into a pliable instrument of policy and the pluralistic view that it must be allowed to go its own way as a fertile but erratic source of potentialities for understanding and action. There is a real risk that in our greed for technological golden eggs we shall try to put this wild goose into a battery and kill it with too much rich food. For three centuries, science has been a magnificent human endeavour; can it survive its own success? □

John Ziman is Professor of Physics at the University of Bristol, UK, and Chairman of the Council for Science and Society.

Limits to scientific growth

F. S. Dainton

Scientific Progress: A Philosophical Essay on the Economics of Research in Natural Science. By N. Rescher. Pp.278. (Basil Blackwell: Oxford, 1978.) £15.

As an undergraduate reading chemistry I found in the College Library a remarkable book by R. G. Collingwood called *Speculum Mentis*. The clarity and cogency of the argument and prose style almost seduced me from chemistry to philosophy. From this temptation I was saved by reading Hishelwood's *Kinetics of Chemical Change* which convinced me that to be a scientific specialist need not exclude other concerns. Why should scientists not have something to say about philosophy and philosophers something to say about science from which their auditors could profit? Now, 46 years later, I recall with pleasure the enlargement of my understanding gained from reading not only the works of past giants but also the works on science and philosophy of many near-contemporaries like Medawar, Popper and Polanyi. I return repeatedly to peruse them and always with profit. Alas, I am also reminded of the growing volume of mediocre work purporting to deal with the philosophy of science, and science policy. Much of these writings obfuscate rather than clarify; their prose is loaded with impenetrable, imprecise jargon—the hallmark of the institutionalisation and decay of an intellectual enquiry—and I put them down never to return to them.

This book does not fit easily into either of these categories. The author is prolix to a degree; printing costs hold no terror for him and if 11 words can be replaced by 4 he is unerringly generous. Thus, for "Figure X illustrates this" he writes "the case is rendered graphic by the picture of figure x" and for "After phase one . . ." we read "once the first phase has been gotten over with . . .". More significantly the book is stuffed with lengthy quotations and with tedious tables and graphs telling the readers what most of them know, namely, that scientific activity, however measured (for example, by numbers of scientists, by their publications, by their costs, by growth of techniques, and so on) has grown phenomenally in the past two centuries.

All this verbage obscures the message which is simple and could be encompassed in one-fifth the space with five times the impact on the reader. The proposition is that scientific progress is not limited either by any intrinsic finiteness or by human cognitive power, but that, although knowledge begets knowledge, which accounts for the near exponential progress of science in the early stages, scientific advances now and in the foreseeable future require even more effort and therefore the deployment of more human, material and correspondingly financial resources. Consequently acceleration gives way to deceleration of scientific advances and the smoothed (for the author acknowledges the episodic nature of discovery on the short timescale) curve of scientific progress over centuries will appear sigmoid. This is not to say that there is an asymptote which is constant so much as having a slight positive slope.

Two features of this conclusion, which I can accept as probably correct though unprovable, are puzzling. First, to whom is the conclusion addressed and what use should be made of it? Governments, their agencies and large private and national corporations who provide the bulk of the money for scientific research already know that it becomes daily more expensive in real terms. This fact rather than the argument of this book is what sharpens their choices and affects their priorities. Will it help the scientists, stimulate their endeavours, quench their enthusiasm or send them off in new directions? I do not know but I doubt it.

What will the philosophers make of the book? I am not competent to express a view as to its philosophical significance though I would guess that it would have a value in slightly deepening their perceptions of the extrinsic factors which now restrain the rate of advance of science but which leave their own subjects virtually untrammelled. Nor will the economists or philosophers of science bat an eyelid for there is no news for them in this book. But it would make useful background material for school teachers, whether of history or of science, and

UNITARY GROUP REPRESENTATIONS
In Physics, Probability, and Number Theory

MATHEMATICS LECTURE NOTE SERIES
George W. Mackey, *Harvard University*

Here are Professor Mackey's well-known Oxford lectures finally in book form. The theory of unitary group representations in Hilbert space is a mathematical tool of considerable power and scope. It includes fourier analysis, spectral theory, and the representation theory of finite groups as special cases and may be regarded as a unification of these. The purpose of this book is to present the main outlines of this theory and then give a rather detailed account of its extensive applications to probability, quantum physics, and number theory.

SCATTERING THEORY in QUANTUM MECHANICS
Physical Principles and Mathematical Methods

LECTURE NOTES AND SUPPLEMENTS IN PHYSICS SERIES
Werner O. Amrein, *University of Geneva*
Josef M. Jauch, *late of University of Geneva*
Kalyan B. Sinha, *University of Geneva*

For mathematicians active in perturbation theory, scattering theory, eigenfunction expansions, rigged Hilbert spaces, and quantum mechanics of many-body systems, the authors explain the concepts of scattering theory, develop the mathematical tools for their description, and derive properties of various physical quantities with mathematically rigorous methods.

Contents: Part I: INTRODUCTORY MATERIAL. Physical Heuristics. Hilbert Space and Linear Operators. One-Parameter Unitary Groups and Free Particles. Part II: GENERAL FORMULATION OF SINGLE-CHANNEL SCATTERING SYSTEMS. Time-Dependent Scattering Theory. Spectral Theory of Self-Adjoint Operators. Time-Independent Scattering Theory. Position in Scattering Theory. Part III: SPECIAL TOPICS IN POTENTIAL SCATTERING. Self-Adjointness, Existence of Wave Operators. Asymptotic Completeness. Eigenfunction Expansions. Spherical Symmetry in Scattering Theory. Scattering at High and at Low Energies. Scattering Theory for Long Range Potentials. Part IV: MULTICHANNEL SCATTERING SYSTEMS. General Formulation of Multichannel Scattering. Multichannel Potential Scattering. The Three-Body Problem. Bibliography. Notation Index. Subject Index.

International Journal
of Breeding Research and Cell Genetics

ISSN 0040-5752 Title No. 122

Managing Editor: H.F. Linskens

Editorial Office: c/o Department of Botany, University, Toernooiveld, 6525 ED – Nijmegen (the Netherlands)

Editorial Board: H. Abplanalp, L. Alföldi, R.W. Allard, S. Barbacki, J.S.F. Barker, D.K. Belyaev, Y.Y. Gleba, Å. Gustafsson, R. Hagemann, Hu Han, R.C. Lewontin, W.J. Libby, J. Mac Key, P. Maliga, F. Mechelke, G. Melchers, B.R. Murty, O.E. Nelson, P.L. Pfahler, R. Riley, F.R.S., A. Robertson, F.R.S., H. Skjervold, P. Spiegel-Roy, H. Stubbe, K. Tsunewaki, L.D. Van Vleck, G. Wenzel, D. von Wettstein.

The publication program of **Theoretical and Applied Genetics** reflects the continuing progress of breeding genetics, including the fundamental and applied aspects. TAG will publish original articles in the following areas:

- Genetic fundamentals of plant and animal breeding
- Physiological fundamentals of plant and animal breeding
- Application of cell genetics to breeding

In placing the general breeding problems in the broader context of general genetical theories and in adjusting to recent advances in the application of cell manipulation in breeding techniques **TAG** will help to meet a real need of publication with a minimum of delay, and serve as a vehicle for international communication on theoretical and practical breeding problems.

This new enlarged program adapts to the changing world of breeding research and covers: genetics on the cellular level, somatic hybridization, genetics of the group, including the evolution and the origin of cultivated plant and animal species.

Besides original papers **TAG** will publish reviews or articles on hot topics of applied genetics as well as critical book reviews covering applied genetics in a wide sense.

The editorial policy is aimed at quick publication by a referee system which enables the authors to send their manuscripts directly to the most competent member of the editorial board. In this manner the manuscripts are guaranteed the best possible editorial handling.

for undergraduates in the liberal arts and science colleges.

The second puzzling feature is that although the author refers to human will as influencing the pace of scientific progress he scarcely touches the more fundamental question as to what potentiates this will, though this is clear enough.

Science like art, music and literature is one of the ways in which man learns more of his own nature especially in relation to the external physical and biological world. The pursuit of science is part of the quest for his own identity. Additionally, scientific knowledge gives him power to use the forces of nature for his own ends and may even change some of the values by which he lives. What seems to me to be important here is whether Western man, whom science has enabled to meet his biophysical needs will opt in the post-industrial society to satisfy his psychosocial needs and what effect this will have on his will to advance science. Even if, as Daniel Bell has indicated, the optional post-industrial society is the learning society, will man want to know more of Nature or more of the nature of Man?

Although I have described the main thesis it should be made clear that in developing it the author refers to other interesting matters. Thus, the importance of technology, even its necessity, for the advance of science is clearly delineated, although the almost inadvertent way in which science can provide the seed of much technology is scarcely developed. There are provoking juxtapositions such as the increasing cost of pollution and the diminishing cost of computers, attempts to provide a taxonomy of subjects and of technological speciation. But even giving credit for these virtues the book is not remotely worth £15 for which price one is entitled to expect the absence of elementary spelling errors such as *polution Wertheimer* (the author of one of 3 "magisterial" reports upon which "the book can be regarded as a philosophic—economic commentary") and George *Babbington* Macaulay whose second page reference in the index I could not find. ☐

Sir Frederick Dainton is Chairman of the University Grants Committee, London, UK.

Universalistic view of science

Stuart Blume

The Reward System in British and American Science. By J. Gaston. Pp.204. (Wiley: New York and Chichester, UK, 1978.) £13.40.

THE most important criticism which can be levelled at Professor Gaston's highly polemical work is not that the arguments it contains are in error (though in some ways I believe them to be) but that it embodies a minimising and depressing answer to the question "what should the sociology of science be about?" No scientist, whether physicist or sociologist, wants his specialty to be defined so as to exclude the questions he finds most interesting. Let me explain, though necessarily at some length.

Some 20 years ago the distinguished American sociologist Robert Merton set out certain rules, or 'norms', of social behaviour to which he believed scientists tended to conform. These norms, a sort of moral code, were seen as uniquely congruent with the goal of science: that is, the advancement of knowledge. (For example, one such norm was 'universalism': the notion that any contribution to science must be judged solely on its scholarly merits, and independently of the nationality, sex, institutional affiliation or age of its author.) Conformity was secured by rewarding 'proper' scientific achievement, both formally (with medals, invitations to serve on this or that) and informally (by citation of work): symbols that scientists came to want. Out of Merton's observations grew a sociological research programme, central to which was investigation of the reward system of science.

Either by personal interview or with a mailed questionnaire, data were collected from groups of scientists. Indicators of each individual's contribution to science on the one hand, and the 'rewarding' or 'recognition' received on the other, were correlated. The point was to see whether such extraneous factors as where the scientist had been trained, or where he worked, influenced the reception his work received, independently of its quality. Some of these studies (including that by Sinclair and myself of chemists in British universities) indeed found such "departures from universalism". (We found that an Oxbridge affiliation (a post at Oxford or Cambridge University) was an advantage in chemistry.)

After reviewing some of these studies, Gaston disputes the interpretation which the authors placed on their findings. His view is that systematic departure from universalistic behaviour is unproven. Moreover, in so far as there is any truth in the previous authors' claims, what is indicated is that the reward system works differently in the various disciplinary and national groups studied.

In the central part of the book (pp55–119) Gaston sets out to see if this is true. Information on a random sample of 600 academic scientists (divided equally between physics, chemistry and biology, and between Britain and the USA) was collected from published sources such as *Chemical Abstracts* and *American Men and Women of Science.* The two countries are seen as exemplifying contrasting styles of organising and funding research, and the three disciplines different levels of "codification" (=development). (For reasons of space I won't take issue with the crude reductionism underlying this view of the relationships between the sciences, nor indeed with the somewhat misleading picture of the British educational and science policy systems presented.) Analysis takes the form of many pages of correlations and regressions, involving such variables as each scientist's number of publications, years of research, 'honours' received, citations to his work, and so on. In brief, the conclusion is as follows. Factors such as sex or the prestige of the university of training or employment make little difference in science. Scientists are honoured, their work cited, almost wholly according to merit: the system is "universalistic". Not wholly so, however, and the differences between the disciplines turn out to be greater than those between the two countries.

Gaston's major conclusion, that science is largely universalistic, implies that science is unique in the modern world: unique not just epistemologically but sociologically too If race, sex, social origins, place of work are irrelevant to the working of the scientific system, this is scarcely true of any other sphere of modern life. The claim that science is universalistic implies (though this is not examined) that scientists' commitments and loyalties, all the things that they are and that concern them when they leave the laboratory, are irrelevant to their systematic interactions with each other. In Britain a public school or Oxbridge education may be an advantage to the physician, the civil servant or the soldier—but not to the scientist. That may seem reasonable, but one can go on. Does it seem as reasonable to hold that to be invited to serve on a top-level advisory committee depends solely on scientific achievement, and not at all on politics or whether someone works in Massachusetts or Wyoming? Women are said to be at no disadvantage in science, and the fact that the sample of 600 included only 3.7% women is nothing to do with science. As this universalism is said to be almost independent of political and organisational contexts of science, it should be

An Introduction to Systems Analysis
with ecological applications
John N. R. Jeffers

The systems analysis approach to handling complex interactions or decision-making is widely used in biology and has been found particularly useful in ecology, which frequently deals with complex communities. After examining the underlying principles of systems analysis and the use of mathematical models, the text is divided to show the various types of mathematical models, in increasing complexity, that can be used for systems analysis. The advantages and disadvantages of each modelling process are described, with numerous worked examples taken from a wide range of topics in ecology.

Biological Identification
Richard J. Pankhurst

This book gives an account of a very wide variety of both traditional and modern methods of identification. Most readers are likely to be familiar with diagnostic keys, which take many forms, and these are discussed in detail. The more modern methods often involve the use of computers and are capable of very accurate and rapid identification in complex groups — as long as a thoroughly tested program is available.

Although Mr Pankhurst has written the book for biologists, the problems and underlying principles he presents are relevant to any identification procedure, and similarly the methods he discusses are as applicable to, for instance, forensic science as to the more traditional problems of field biology. Thus the book will be of value not only to biologists at all levels, but to anyone who regularly encounters problems of identification.

Paper £3.20

hard to conceive of a country in which the honouring of a scientist's work could be influenced by any dissident views on political matters which he or she may hold.

It is a fallacy to believe that people's concerns, loyalties and commitments are so rigorously compartmentalised: that the fact of parenthood is irrelevant outside the home, or of political commitment outside organised politics. If these things are indeed irrelevant in science, then surely those who hold this to be so are by now obliged to prove how and why this is and remains so. The onus of proof must be shifted.

The divergence of view between Jerry Gaston and I derives in part from our different methodological preferences. What is to count as evidence? Should we correlate membership of the Royal Society, the US National Academy of Sciences or the Soviet Academy of Sciences with "number of papers published" — or should we try to probe how, and on what basis, these bodies actually elect members?

We differ also on what we want our subject to be about. On page 14 it is stated "Scientists cannot be totally motivated to conduct research by the level of monetary rewards". But are they totally unconcerned? Is the growth of trades unionism among scientists wholly irrelevant (to sociologists)?

The depressing thing for me, then, is the implication which the book embodies as to what the sociology of science is to be about. If the subject is about the operation of the "reward system in science" — indeed central to the research tradition which Gaston so proudly espouses — and if this works virtually independently of socio-political environment, then what should sociologists of science do? There is little point in studying the way the system works in a traditional society like India or a culturally divided one like Canada. Yet interesting work of this kind is being done. There is little place in such a sociology for studies of the way in which intellectual and social changes in a discipline interact with each other over time. Yet here, too, fascinating work is being done by sociologists, historians and philosophers working together. A crucial test of any research programme must be the range and the interest of the problems for research which it generates. However convincing his statistical correlations, on this test Professor Gaston's work falls. ☐

Stuart Blume is Senior Research Fellow in the Department of Sociology and Psychology at Chelsea College, University of London, UK.

Lifeboat or country club?

Thomas H. Jukes

The Limits of Altruism: An Ecologist's View of Survival. By Garrett Hardin. Pp.154. (Indiana University Press: Bloomington, Indiana, and London, 1978.) $10.

ALTRUISM is a fascinating and inexhaustible topic for writers. The betrayal of kindness by ingratitude is a recurrent and compelling theme in drama. Throughout human affairs there runs a curious and shifting equilibrium between selfishness and generosity, but, as Hardin notes (p79) starvation puts an end to altruism. Human actions divide into opposing categories of egoistic and altruistic.

For some years, Hardin has discussed problems of exhaustible resources, often in terms of analogies. One of the themes is that of a shared pasture that becomes irreversibly depleted by overloading with individually owned grazing animals. This is well illustrated by the current international depletion of oceanic fisheries. In *Living on a Lifeboat* (p142), Hardin says that "To avoid unconscious suicide, we are well-advised to pit one metaphor against another". His lifeboat metaphor, which surfaces again in *The Limits of Altruism* (p62) says that it is foolish for the well-to-do nations, living in lifeboats, to go on welcoming members of the impoverished nations aboard. The lifeboat will sink with all hands.

However, I think that inhabitants of the impoverished countries are apt to counter with another metaphor. The prosperous nations remind them of the wealthy members of a country club who have closed the doors to outsiders because the golf course and the dining room might become crowded. Does anyone believe that we in the developed countries can keep the swimmers around us from climbing aboard the lifeboat—or from overturning it? Hardin evidently believes this. He says that we should "preserve enough of the economic and social barriers between groupings of humanity so that the cancer of collapse can be localised" (p84).

He states with emphasis that "Selection is not, by its nature, for the good of the species. The survival of the species is an almost accidental by-product of the survival of germ lines" (p107). However, it is obvious that germ lines cannot survive if the species becomes extinct, so therefore survival of the species cannot be an "almost accidental by-product".

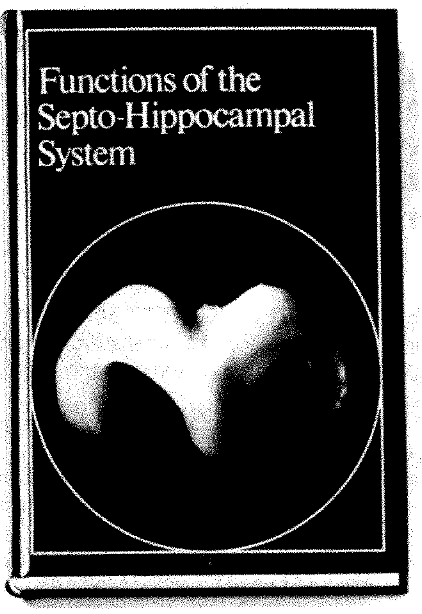
Phosphorus, in large amounts, is essential to life: in photosynthesis and metabolism; in DNA, bones and all cell membranes, and in fertilizers. It can also pollute and, in certain forms, it can kill. At this international symposium chemists, biochemists, limnologists, agricultural scientists and policy makers from government bodies, universities and industry discussed the resources, costs of extraction, chemistry and biochemistry of this element, its role in fertilizers and detergents, the problems it can cause in sewage and waterways, its effect on the environment, and ways to control its uses.



FUNCTIONS OF THE SEPTO-HIPPOCAMPAL SYSTEM

Ciba Foundation Symposium 58
1978 446 pages
US $43.50/Dfl. 98.00 ISBN 0-444-90032-2

The septum and hippocampus are anatomically well defined but their functions remain mysterious. They are said to play a role in learning, memory, and habituation to novel stimuli. This symposium is the first of its kind to consider the two structures together, in an attempt to build up a picture of septo-hippocampal activity. The volume should be of great interest to neuroanatomists, psychopharmacologists, neurophysiologists, psychologists and neurobiologists.

NEW from MIT

Rat Hepatic Neoplasia

editors Paul M Newberne & W. H. Butler

Although there has been much study of rat hepatocarcinoma over many years, there has been no general agreement on the histologic criteria for evaluating the biologic significance of the neoplasm or of the lesions that precede it, nor has there been agreement on the relation between 'premalignant' and malignant lesions. This book aims to establish a more exact definition.
Ten chapters (updated papers/originally given at a Workshop at Woods Hole) cover such subjects as embryology and aging of the rat liver, hepatic nodules, sequential cellular alterations during heptacarcinogenesis, microsomal enzyme systems and drug toxicities, light microscopy of neoplasias, the ultrastructure of hepatic neoplasia, hepatocellular growth control, cultures epithelial-like cells, the immunology of neoplasia, and the effects of diet on carcinogenesis.
14029 2 £15.70 published November.

The Mindful Brain

Cortical Organization and the Group-Selective Theory of Higher Brain Function.
Gerald M. Edelman and Vernon B. Mountcastle.

The Authors examine from different but complementary directions the relations that connect the higher brain functions — memory, learning, perception, thinking — with what goes on at the most basic levels of neural activity, with particular stress on the role of local neuronal circuits. Edelman's major hypothesis is that the brain functions as a selective system in which the unit of selection is a neuronal group which is part of a large repertoire formed during embryogenesis; Mountcastle reviews what is known about the actual structure of the neocortex, relating the various parts to their component modules, the local neuronal circuits.
0 262 05020 X £7 published October.

Beyond the Moon

Paolo Maffei
D. J. K. O'Connell.

Beyond the Moon is a fascinating travelog describing a voyage of scientific imagination from the moon to the outer limits of space. This grand celestial tour is not only an engrossing story (six editions so far in Italy) but an accurate description of what is currently known about the universe: Maffei is a professional astronomer, discoverer of two galaxies that bear his name and the translator D. J. K. O'Connell was formerly astronomer to the Vatican. This edition, revising and updating the Italian book, includes the findings of the space probe on Mars and around other planets. Over 120 astronomical photographs, drawings and diagrams.

0 262 13133 1 £8.75 published November.

Elementary Crystallography

An Introduction to the Fundamental Geometric Features of Crystals.
Martin Buerger.

The MIT Press is reissuing the revised edition of this work (the original Wiley edition is now out of print) because it is considered the classic exposition of a subject basic to all the sciences and because the book has not dated: it remains the most comprehensive treatment of crystallographic symmetry ever published.
0 262 52046 6 paper £8.75 published November.

Science Textbook Controversies and the Politics of Equal Time

Dorothy Nelkin

" . . . there is a mine of information and careful documentation here. The story is well told and is absorbingly interesting. The book is a most useful addition to the literature on curriculum change and social climate and on pressure groups in science education." Nature.

Investigative Mycology

Robert F. Sharp

with drawings by Keith James

Fungi, with their wide variety of colours, shapes, tastes, smells, and healing and destructive properties, are fascinating organisms, but are too often treated as mere curiosities. *Investigative Mycology* is a guide to the scientific study of fungi. It contains many simple experiments on conditions for growth and decay, an examination of structure, and a variety of measurements to aid the classification of different species. Most can be performed easily and require no technical expertise. The book is full of useful information concisely presented, and has numerous clear, artistic drawings. A short history of mycology accentuates its relationship to the more general sciences.

NELSON announce a new edition of an influential text.

Invertebrate Structure and Function Second Edition

E. J. W. Barrington

THIS MUCH RESPECTED TEXT provides a comparative treatment of animal structure and function as exemplified by the invertebrates.

THE SECOND EDITION OFFERS a considerable amount of new material on invertebrate movement, chemical communication, and animal association. Reworking various passages has allowed a more explicit treatment of the experimental analysis of function. More than 170 new figures and tables have been included.

Circle No. 53 on Reader Enquiry Card.

In our species, says Hardin, selection occurred on a tribal basis. Altruism was practised within the tribe, and non-members of the tribe were exterminated (p112). Yet today (p127) "we continue to fling money desperately at poor countries half a world away, hoping for miracles" . . . "If we desire a world in which altruism can persist, we must reject the ideal of One World . . ." (p132). Whether such a rejection is feasible is not clear. ☐

Early Victorian science

David Knight

Science in Culture: The Early Victorian Period. By S. F. Cannon. Pp. 296. (Neale Watson: New York; Dawson: Folkestone, UK, 1978.) $17.95; £12.50.

It was with a plea for history in depth, published in 1964 and revised as a chapter of this book, that Dr Cannon made a reputation; as befitted the journal *History of Science* in which it appeared, this was partly a review of recent work, partly a discourse on method, and partly an elucidation of an historical event. The various chapters of this book are all of rather the same kind, several others being revisions of articles; together they form a rather curious and loosely organised but very stimulating book, which poses more questions than it answers. Some chapters are very informal, and read like lively contributions to a seminar; thus, on one page "Thomas Kuhn" is introduced in one paragraph, and becomes successively "Thomas" and "Tom" in those that follow it. In sundry asides, we learn something about the author; for example, *apropos* of a discussion of professional success: "It is nicer to sit at the top of a new multi-million dollar building in a world-famous institution and let the seekers come to you. This is what I do". The founders of the British Association might perhaps have felt something like that, though they would have blushed to write it.

Dr Cannon's desirable office is at the Smithsonian, and one might expect that museums would occupy a prominent place in her discussion of early Victorian science; but they do not. In general, botany and zoology, and the world portrayed in D. E. Allen's *The Naturalist in Britain* (1976) get short shrift; also omitted is discussion of medicine, in which men of science (even physical science) were trained and which was undergoing professional reorganisation during Dr Cannon's period. Nor is chemistry seriously discussed, although it could have been, as Colin Russell *et al.* have shown in their *Chemists by Profession* (Open University Press, 1977). Morris Berman, in his *Social Change and Scientific Organisation* (Heinemann, 1978) presents the Royal Institution as a temple wherein Day and then Faraday, apostles of applied science, preached to improving landowners; but applied science is not one of Dr Cannon's interests, and the reader will find little to remind him that Britain was in the throes of industrialisation, or that important educational centres were being founded in London and the provinces.

Dr Cannon is exposed, as anybody who advocates the ideal of history in depth must be, to anybody who cares to point to what she has left undone; but if the historian really had to take everything into account before he or she wrote anything, then the discipline would wither away. So it is within its limitations, as an account of what she calls the "Cambridge Network", that the book should be judged; and there it is illuminating. This is upper-crust history; her protagonists share an admiration for Broad Church doctrine and physical astronomy, and are professionals in the lofty sense that they pose the questions which the ordinary cultivators of science then try to answer. This view of professionalisation gives one a moderately testable version of Kuhn's idea of paradigms, and Dr Cannon's discussion, in general terms and applied to the founding of the British Association, is most interesting. John Herschel is particularly important in her study, and she makes out a good case for her remark that to agree with him "was considered a mark of good sense in early Victorian England".

For her, Herschel and his associates in the "network'—of which Faraday was a kind of honorary member—played a vital role in bringing to birth what we call 'physics' out of natural philosophy by Humboldtian observational science. She admits in a note that this is a partial view, and that steam engines had something to do with it too, but her part of the story is fascinating, and here as elsewhere hoary myths are elegantly shown up. Her suggestion of most general interest is that up to the 1850s in Britain there was a single view of truth, with science, religion, literature and history being complementary, and Newtonian astronomy the accepted model of demonstrated truth. She sees this golden age

Studies in Biology

100 volumes, a million sales

Edward Arnold are pleased to announce that in the same year as publication of the 100th Study in Biology, the sales of this series will exceed one million.

'Overall this series has probably been more successful than any other which has been attempted. The secret of its success lies in the publisher's skill in the selection of topics and determination of length (and, thereby, cost) . . . The series provides a medium by which biologists can be kept up to date with developments in specific areas of biology. They are reasonably priced and are an ideal way by which individuals, schools, colleges and universities can supplement their libraries in particular fields.' —*Nature*

'In 1966 the Institute of Biology launched the first few titles of "Studies in Biology". Ahead of many imitators, their aim was to produce a solution to the problem of rapidly expanding biological knowledge and out-of-date textbooks. The proposed booklets were to range widely over the field of modern biology, presenting authoritative texts in a form attractive to sixth formers and undergraduates . . . the success of the venture and the reputation of the series is firmly established. Many are required reading for courses at colleges, schools and universities. More important still has been the use teachers have made of them to update their knowledge, enabling them to impress upon their pupils the expanding nature of the science. . . . these books remain the very best of their kind on the market.' —*New Scientist*

A full list of the titles in the "Studies in Biology" series is available from Edward Arnold Ltd.

or era of good feeling collapsing in 1859 when Darwin published the *Origin of Species*, and not merely two but a whole series of cultures emerged, each with its own experts, or professionals, and tests of truth. This is interesting, and may be true; but if so, it would only show that events in England moved more slowly than they had in France or Germany, where the process had begun much earlier. One may also suspect that a focus on her Cambridge men—a group dedicated to the unity of knowledge—makes one attribute too much importance to them, and especially to Darwin, who appears here as the only star of any magnitude in the life sciences; Huxley comes in as his accompanist, rather than as the introducer of the revolutionary new physiology from the Continent. In the decade before 1859, religious doubt had spread widely in Britain, and novels describing it had become a *genre*; men such as Frank Newman and J. A. Froude were prominent agnostics owing little or nothing to Darwin or his circle.

One may suspect then that some of Dr Cannon's generalisations apply not far beyond the limits of her "network"; but like the professionals she describes, she poses questions that will set others thinking for some time (and indeed have already done so) and she makes methodological remarks of great value to anybody interested in the history of science. □

Foster's school

R. K. French

Michael Foster and the Cambridge School of Physiology: The Scientific Enterprise in Late Victorian Society. By G. L. Geison. Pp.401 (Princeton University Press; Princeton, New Jersey, 1978.) £18.40.

HERE is a biography of Foster and an account of the Cambridge School of Physiology. It is not, as the subtitle suggests, about *The Scientific Enterprise in Late Victorian Society* as it is limited to "one small group of English physiologists . . . between 1870 and 1900" (preface).

Although we are not far removed in time from late Victorian science, there is still a great deal we do not know about some of it, including physiology: Geison's book is a step in the right direction. Modern fashions in history range from history of ideas to sociological history, and historians, if not the readers of historical books, look for more than the old-fashioned Life and Times biography. But only rarely have we enough information to make the most of both of these approaches.

The format of this book is determined partly by the demands of social history, but the book itself is something of a pilot study in an area which, as Geison insists, is still very little known. The result is that these modern historical tools cannot be used effectively, and the text gives the impression of being somewhat over-written, a little bit 'stretched'. Another reason for this is the book's origin as a dissertation.

The copious text is subdivided by elaborate headings, which suggest a somewhat laboured reworking of the material. The reader might even be well advised to read first the "Concluding Reflections" which so lucidly and tersely tie together the strands of the book that they are an indispensable guide to the detail and documentation of the earlier pages. These are naturally more exploratory than books written later in life. In his exploration Geison has uncovered a problem with Foster and has made valuable progress in seeing how it is answerable. Foster's reputation is that of a man with great influence on his subject and at the centre of its institutionalisation, yet the further the evidence and explanations for this are pursued the more elusive they become. Perhaps this problem can be historically generalised as the 'Boerhaave problem'. Boerhaave was one of the most renowned medical teachers of all time, yet the reasons for his influence are difficult to pin down. He made no major discovery and his teaching contained few innovations. His successful synthesis of current systems must be part of the answer, but the resultant bland and conservative doctrine does not convince even the historian of ideas that it was the complete answer. Such a historian is compelled to use other techniques.

Geison's problematic Foster faded early as a research physiologist without having produced "a signal piece of research of the first order", and as the quotations prefixed to Geison's introduction show, neither contemporary or later historical opinion could in any concrete terms explain Foster's influence even by reference to his teaching. So, even though the problem calls for new historical techniques, the evidence is insufficient for their use. Geison's attempt to use them is dutiful but not always productive; at one point he is "ready to give up in despair" (p143) in attempting to solve the "mystery of Foster's achievement [which] can never be entirely dispelled" (p188). In attempting to dispel it Geison very usefully investigates Foster's work on the myogenic origin of the heartbeat, his characteristically English evolutionary view of physiology, which form a strong 'history-of-ideas' theme for the book, and his tactics to promote his 'school'—for example his publication of his student's papers. Much more hypothetical is Geison's brief and flirtatory parallel between on the one hand the politics of Bismarckian Germany, Czarist Russia, and the neurogenic 'autocratic' theory of heartbeat, and on the other, the opposing, innate, non-centralised 'democratic' myogenic theory, and Foster's role therein.

Readers of *Nature* will probably find these remarks too carping, and will certainly find the book itself a very welcome piece of work, carefully researched, dealing with an important topic and necessarily interesting to modern scientists and historians. □

Oxford Books for Students

Physical Chemistry

P. W. Atkins

'What convinces me that this is a book that should be widely adopted, and which will be sought after by undergraduates whatever their teachers may recommend, is that the whole work is distinguished by penetrating insight allied to consistent and exceptional clarity of expression. *The Times Higher Education Supplement.* £15 paper covers £7.95

Primary Metabolism

A Mechanistic Approach

J. Staunton

The traditional line of demarcation between biochemistry and chemistry has dissolved in recent years as chemists and biochemists have joined forces in investigating the mechanisms of reactions which take place in living systems. This book introduces this area of common interest to students of both chemistry and biochemistry. £6.50 *Oxford Chemistry Series*

Secondary Metabolism

J. Mann

This book is concerned with the biosynthesis, biological activity, and ecological significance of secondary metabolites (natural products). All the major classes of secondary metabolites are considered systematically, according to the basic 'building blocks' from which they are derived. £9.75 *Oxford Chemistry Series*

Numerical Solution of Partial Differential Equations

G. D. Smith

This substantially revised second edition covers linear and non-linear parabolic equations, the analysis of errors, first- and second-order hyperbolic equations, elliptic boundary-value problems, systematic iterative methods, consistent orderings of matrices, and recent methods for large linear systems. Second edition illustrated £9 paper covers £4.95 *Oxford Applied Mathematics and Computing Science Series.*

The Bowels of the Earth

John Elder

This paperback reprint has replaced the boards edition which was published in 1976. 'Original, persuasive, intensely individual . . . . the book is plainly a *tour de force*, and it may set a new model for scientific exposition . . . . The prose . . . . is direct and evocative.' *Scientific American.* Paper covers £2.95

Human Growth and Development

Wolfson College Lectures 1976

Edited by Jerome S. Bruner and Alison Garton

These papers explore some of the biological, social, and political factors involved in growing up in modern society. They indicate the strong admixture of biological and social determinants that influence behaviour during child development, and two main themes run through the book: the importance of achieving social connection, and the active nature of childhood. £4.25 paper covers £2.25

Mechanics and Motion

L. Mackinnon

This book, based on the first-year course given by the author at the University of Essex, provides a survey of those topics that are an essential background to modern physics and advanced engineering. Throughout, the emphasis is on the basic physical concepts necessary to a study of the more advanced courses that will follow. £6 paper covers £3.25 *Oxford Physics Series*

The Properties of Nuclei

G. A. Jones

This book describes the properties of nuclear levels, starting with stable states and progressing, via quasi-stable states (radio-active ground states and nuclear stable excited states), to unstable (nucleon-emitting) states. The shell model, the collective models, and the optical model of the nucleus are described, and nuclear reactions are introduced in terms of the compound nucleus and direct processes. £5.95 *Oxford Physics Series*

Announcing a Major New Journal

Immunology Letters

CALL FOR PAPERS

for the rapid publication of short reports
in Immunology

Aims and Scope
The journal will provide a vehicle for the rapid publication of short, complete and definitive reports of work in all aspects of immunology. The essential criteria for publication will be clarity, experimental soundness and novelty. Results contradictory to current accepted thinking or ideas diverging from actual dogmas will be considered for publication provided that they are based on solid experimental findings. Preference will be given to papers of immediate importance to other investigators, either by their new methodology, experimental data or new ideas. Commentaries and replies related to the published reports may also be accepted provided that they are short (maximum 700 words) and scientifically relevant to the reports mentioned, in order to provide a continuing forum for discussion.

EDITORIAL BOARD: **J.F. Bach.** *(France).* ASSISTANT MANAGING EDITOR, **G. Bordenave,** *(France).* MANAGING EDITOR, **A. Bussard** *(France).* **F. Celada** *(Italy).* **B. Cinader** *(Canada).* **A.J.S. Davies** *(England).* **V.P. Eijsvoogel** *(The Netherlands).* **F. Franek** *(Tchecoslovakia).* **J. Gergely** *(Hungary).* **J.C. Howard** *(England).* **H. Fragments of Chargaff

Jerry Donohue

Heraclitean Fire: Sketches from a Life Before Nature. By Erwin Chargaff. Pp.252. (Rockefeller University Press: New York, 1978.) $13.

IT seems appropriate to set the stage of this review with a quotation by the author, one which gives a bit of insight into the character of the character that will be dealt with:

> "I cannot but find it remarkable that almost all the recognition my work received has come from Europe".

Why does he, full professor and department chairman at Columbia, awarded two Guggenheim fellowships, elected to the US Academy of Sciences, recipient of the National Medal of Science (and that's no *petite pomme de terre*) think this? Perusal of the *Citation Index* for the years 1965–68, to choose a few years at random, shows three or more columns of entries for all four years, from predominantly American journals—is not citation recognition? Then why, in 1970, did he submit an important essay, in German, to an obscure German monthly, and eventually publish it in not quite so obscure Swiss journal? This same essay was later translated into English, published in *Science* (**172**, 639; 1971), and in this form "became, perhaps, the most widely read of my articles."

This book was easier to read than to review. The first time I read it, I, well, detested it, and the further into it that I ploughed, the more I was distressed by the author's naïvité, self-pity, anti-Americanism, propensity to quote in foreign languages, inveterate name-dropping, recondite vocabulary, and much more. However, the second time around I found myself trapped into admiration of his observations on: Science (the field, not the weekly tabloid), scientists (some of whom, alas, are only alluded to and not named), Columbia University, molecular biology, current research conditions, DNA, and many more, as well as his piercing personal opinions on almost everything. But more of these later.

One especially valuable feature is the inclusion of a name index, with identifications, which runs to nine pages. However, it is unfortunate that not all of the names dropped in the text are indexed. Furthermore: is it really necessary to have such entries as:

> "Carter, Jimmy—US president
> Ford, Gerald R.—former US president
> Hitler, Adolf—Austro-German politician
> Michelangelo Buonarroti—Italian artist

'Twould have better to have pruned out the obvious, such as those above, plus a plethora of more, and to have included most of those omitted, such as Biedermeier, Consden, Doniger, Gordon—where and who are they now? Other names found in the text were also unindexed; should not these have been included? for example:

> Khan, Genghis—Mongolian politician and explorer
> Terrible, Ivan the—developer of Siberian real estate
> God—Supreme Deity

Because of the fragmentary nature of this book, I decided to cast this review in the form of numerous excerpts, letting the author largely write his own review, so to speak.

Language, and use thereof

Chargaff has a decided tilt towards quoting titles, phrases, sentences, and long (sometimes very long) paragraphs in foreign languages. These are often, but not always accompanied by translations, some of which are unnecessary, for example, *Radetzkymarsch*= Radetzky March. (This may be the fault of his copy editor, that bane of authors who wish to write in their own style.) I noted passages in German (his favourite), French, Latin, Russian, Greek, Danish, Spanish, and Italian; Chinese is conspicuous by its absence, as are Finnish, Hungarian, and Romansch. His vocabulary in English is nothing less than esoterically florid. Consider the following words: aleatory, antinomy, avernal, biopoiesis, bourdon, chiliast, epigonic, hieratic, maieutic, mephitic, phalansteries, polymathic (I stopped at one dozen). If these send you scurrying to your Webster, join me at the bottom of the class.

Whether he is fluent in all of the above tongues I do not know. He admonishes:

> "Reading Ronsard [French poet] or Goethe [German writer] or Blake [British poet and artist] in translation amounts to listening to a transcription of the B Minor Mass [by Bach, German composer] for the ocarina."

He refers to K. Kraus,

> "probably the wittiest writer in the German language": "He considered language as the mirror of the human soul, and its misuse as a forerunner of black and evil deeds. A grammatical haruspex, as it were he read the barbarous and bloody times to come in the entrails of the daily press."

Totally charming.

And who cannot be engulfed by such liquid prose as:

> "I tell what I am told. Who is the speaker? If it is memory, then why does it sometimes whisper, sometimes shout, often chatter, and mostly remain in sullen silence? Ancient telephone numbers from my parents' apartment in Vienna are followed incoherently by the timid half-smile on a little girl's face, and I am eight. Busy ghosts with briefcases run through corridors that no longer lead anywhere. Blind mirrors reflect frightened faces; a bright-red satanic mill engorges bodies and excretes packages of phosphates; gold teeth are sorted, numbered, and melted down; all this to the accompaniment of the sweet and labyrinthine music of the fourth act of *Nozze di Figaro*. It is all in pieces, but the broken edges cut, and there is blood everywhere."

But then we find this sentence, also referring to K. Kraus:

> "The syntactic cataract of his periods, delivered in a specially pointed voice, was an ambush, hiding associations of a shockingly unexpected immediacy."

Now what on earth does that mean?

Also mysterious is his characterisation of the untranslatable (he says) German word *Greis* as

> "so expressive in its diphthongal despair." (?)

On scientists

> "A few years ago, I reviewed a scientific autobiography, a shallow best-seller. In my article [unfortunately not included in the bibliography, although at least one book review *is* included, so the identity of the 'shallow best-seller' can only be guessed at] I had something to say about this species of book, and this I should like to repeat here . . .".

We read that he finds these

> "a most awkward literary genre," [that] "most scientific autobiographies that I have seen give me the impression of having been written for the remainder tables of the bookstores," [and that] "scientists write their life's history usually after they have retired from active life, in the solemn moment when they feel that they have not much else to say. This is what makes these books so sad to read: the eagerness has gone; the beaverness remains . . .".

This book has neither. To be anti-anthropomorphic, Chargaff appears as a mongoose, warily circling the cobras of the scientific establishment, feinting, but ready to strike without warning at the numerous vulnerable points, and it all makes very interesting reading.

> "Great scientists are particularly worth listening to when they speak about something of which they know very little; in their own specialty they are usually great and dull."

There are notable exceptions to this, of whom Linus Pauling is perhaps the most notable; Chargaff himself is another, as evidenced by this very readable book, the fact that you must have your Webster at hand notwithstanding.

> "Most people I meet in my or other universities seem to be rejects from IBM. In fact you can talk with them only in triplicate. Slaves or prisoners of NIH or NSF, of Xerox or Beckman—they are really the narrowest, the dullest kinds of experts or specialists; they are essentially molecular podiatrists: people who know all about the fifteenth foot of the centipede."

Passages like this make me wish that there was some way for Chargaff to reach a larger audience than this book will, to get his messages across. Appearing on TV talk shows to plug the book, as the author of a 1968 scientific best-selling partial autobiography did, is not the answer.

> "In general, there are few things as lugubrious as the professional travels of scientists. This has to do with the professionalisation of our lives and with the unstated, unacknowledged, and possibly even subconscious, cultural imperialism of America. Wherever one goes, the same form of pidgin is spoken, the same cocktails, the same indigestible food, the same centrifuges, gradient makers, the same graphs, all superimposable. After some time, all lectures form one confluent blob; all lecturers stumble through the same ten minutes of automatic recitation; all problems are chattered to pieces, and then coalesce again to the same meaningless phrase, something like 'structure and function.' The brutal clatter of a nonsensical machine engaged in the so-called dissemination of scientific information overwhelms all thought and imaginativeness. Diogenes with his lantern, looking for a human being, would be out of place in these assemblies."
>
> "For instance, the National Academy of Sciences [of which Chargaff has been a member since 1965], which is, after all, only a sort of Chamber of Scientific Commerce into which some very funny characters have entered through various backdoors, is widely regarded as the true receptable of wisdom."

It would have been very interesting if Chargaff had appended a list of these very funny characters, together with their backdoors.

Some nuggets on molecular biology

> "One of the obnoxious dogmas to which it [molecular biology] has given rise—the so-called Central Dogma: DNA makes RNA; RNA makes proteins—is no longer valid . . . But the fact that dogmas could be handed down from the mountains [there are mountains in Cambridge?] shows that science had changed disastrously".
>
> "The definition of molecular biology, given there [in the dialogue *Amphisbaena*, a writing of his not included in the bibliography], as 'the practice of biochemistry without a license' has become well known and much quoted."
>
> "One particularly crude sentence graced the beginning of one of the lectures (the italics are mine) [at a small symposium on biological macromolecules in 1961]: 'The essence of the dogma, *so acceptable to our time*, can be briefly summarized by the following diagram: DNA→RNA→Protein.' (It had not been acceptable to me; but then, I am not of 'our time'.) . . . Actually, this particular dogma, on which free-thinkers and believers could agree so joyfully, has worn unusually poorly. Only a few years later, the peddlers flourished by hawking the reverse dogma".
>
> "There are even some confused people who believe that what is now called 'molecular biology' makes up all the science of life."

On Columbia University

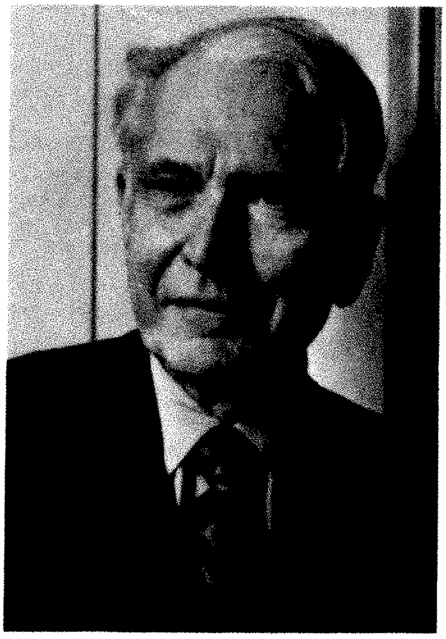
To an outsider, Chargaff's views on the institution where he was on the staff from 1935 until his retirement forty years later, are nothing less than astonishing. Thus:

> "Several [graduate students] already [in 1935] had reached distinction or were soon to do so, although the university showed little recognition of this fact: an old Columbia habit".

And:

> "Many years later, when I occupied the tabouret of biochemistry at Columbia, which in Clarke's time was still a real Chair, I wrote the firm [Eastern Kodak, where Professor Clarke, previous to becoming chairman at Columbia, had spent 14 years developing the imposing line of organic chemicals then and now sold by that firm], suggesting that they help us in setting up a professorship in Clarke's honor. The answer I received will remain a monument to corporate shabbiness".

Although this is less of a blast at Columbia than at Eastman Kodak, the least EK could have done was to have contributed towards a footstool, but that Chargaff chose not to publish that "monument" is regrettable.



Erwin Chargaff

Photo: Rockefeller University Press

And more:

> "What made Columbia, during all my time, such a singularly disagreeable institution is difficult to explain".

Still more:

> "Incidentally, I now have a simple method by which I can recognize future Columbia vice-presidents and deans, especially at the medical school: They misuse the adverb 'hopefully'; they 'address a problem'; they speak of 'input' as if they were dealing with a computer; they submit proposals as 'a package,' but if 'a package' is offered to them, they 'don't buy it'; they like to engage in a 'dialogue'—with several hundred people at the same time—but if you answer, they tell you that this is 'only semantics'." [Loud cheers]

Yet more:

> " . . . I was dismayed to find that my pension amounted to less than 30 per cent of my last regular salary".

What kind of an *Elfenbeinturm* was this man living in? Did it never occur to him to ask someone? Granted that university bureaucracies are notoriously uninformative and mushy, it is, after some effort, possible to extract facts from them.

And finally:

> "On November 20, 1975, the movers came. Certain things had to be left behind because they required individual attention, especially a cupboard full of my own old preparations. When we returned, we could not get into the laboratories. We were told that all locks had been changed at somebody's order . . . And since at Columbia one left hand never knows what the other does, it was quite fitting that less than six months after they had changed the locks on me at the Medical School, the University gave me an honorary doctorate".

The distinct impression is that the walls of Columbia are covered with *Rhus toxicodendron* instead of the *Parthenocissus quinquefolia* of her seven sister institutions.

On DNA and related matters

Chargaff describes the results of his early analyses:

> "The regularities of the composition of deoxyribonucleic acids—some friendly people later called them the 'Chargaff rules'—are as follows: (a) the sum of the purines (adenine and guanine) [A+G] equals that of the pyrimidines (cytosine and thymine) [C+T]; (b) the molar ratio of adenine to thymine equals 1; (c) the molar ratio of guanine to cytosine equals 1."

He later refers to this paper as

> "my ancient review article on nucleic acids, *announcing* the observation of the complementary relationships in DNA" (emphasis added).

First, if (b) A=T and (c) G=C, it immediately follows that A+G=T+C, so (a) is redundant. Next, let us look at the paper in question, the title of which is *Chemical Specificity of Nucleic Acids and Mechanism of Their Enzymatic Degradation*. The only molar ratios presented in the tables are A/G, T/C, and A/C, never the crucial A/T and G/C. Hidden away in the text is the sentence (emphases added):

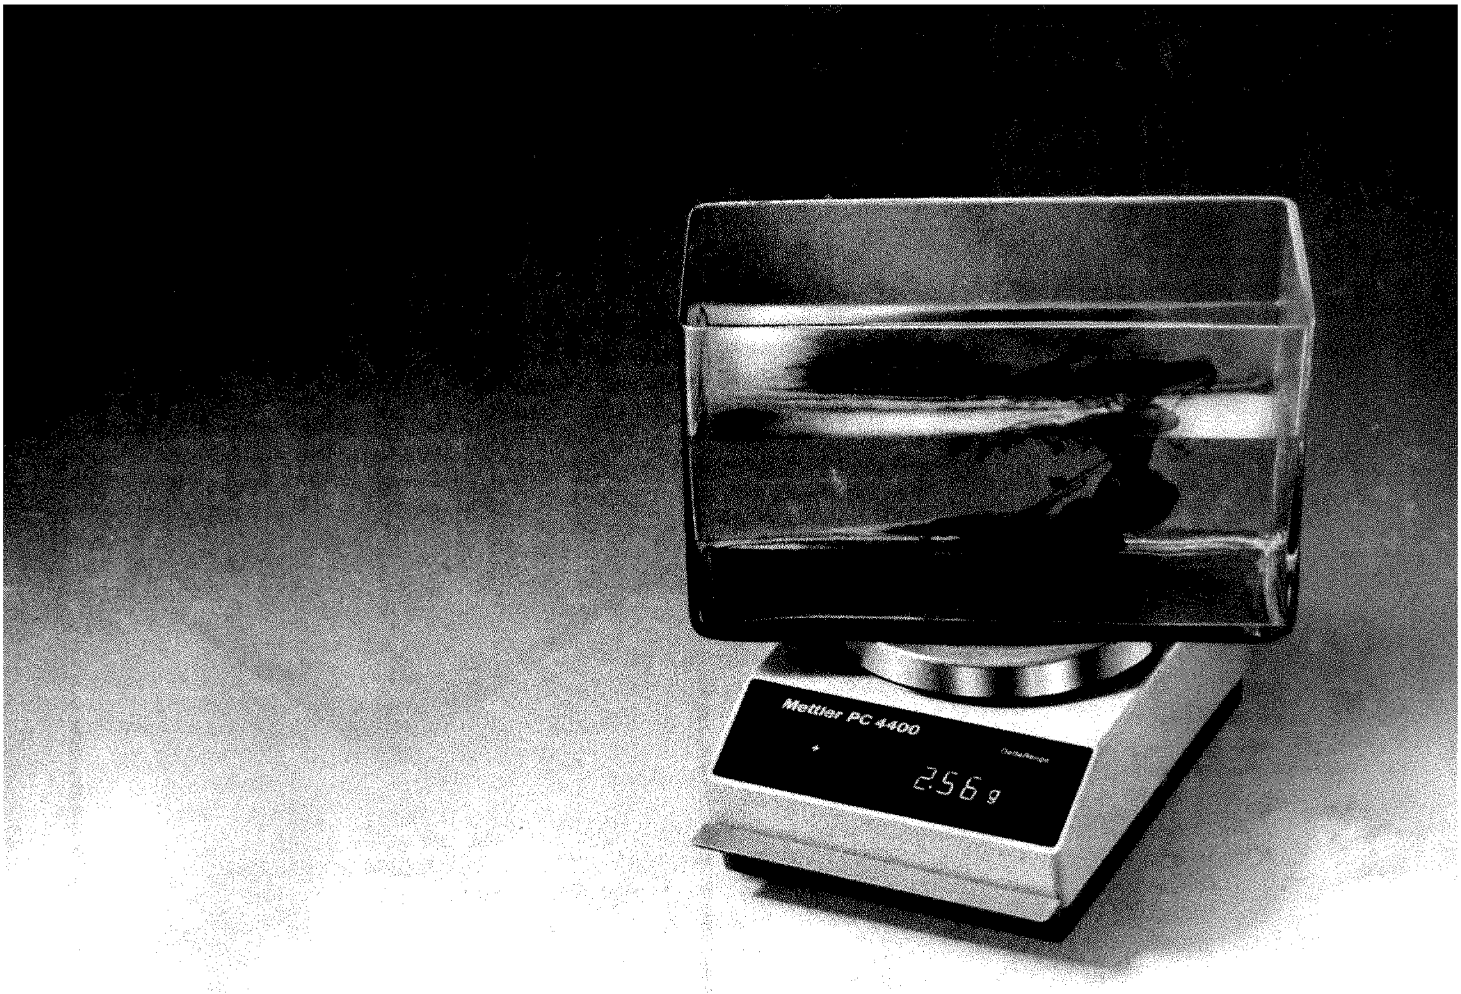
> "It is, however, noteworthy—*whether this is more than accidental, cannot yet be said*—that in all desoxypentose nucleic acids examined thus far the molar ratios of total purines to total pyrimidines, and also of adenine to thymine and of guanine to cytosine were *not far* from 1." [Calculations with data in other tables gives A/T values of 0.90 to 1.20, and G/C values of 0.94 to 1.33].

This hardly seems an *announcement* of complementarity.

This 1950 paper was based on lectures given in 1949. In 1951 there is another paper (*Fedn Proc.* **10**, 654) in which, after noting that A/T and G/C are both "near 1," and (A+G)/(T+C) is "never far from 1," he remarks "whether these are *merely accidental* cannot yet be decided" (emphasis added).

In a 1952 paper, Chargaff *et al.* (*Biophys. biochem. Acta* **9**, 402) give analytical ratios of, among others, G/C of 0.85, 0.90, and 0.93 for DNAs of several microorganisms, results hardly reinforcing the 'rules' with great vigor.

Who, according to Chargaff, made use of his rules? We now move to the



An unconventional balance with an extra measure of accuracy

Mettler DeltaRange breaks through the boundaries that used to restrict the capacity/accuracy ratios of conventional weighing instruments. And Mettler PC electronic top-loading balances are equipped with this new *Mettler DeltaRange* feature.
Just press the control bar of the Mettler PC4400, for example, and you get a 400 g fine range with readings that are 10 times as accurate as those in the coarse range. And you can do it as often as you wish, at any point of the entire weighing range. That is to say, whenever and wherever a 0.01 g readability is needed. On a balance that has a capacity of no less than 4000 g!
In practice, this means that you can use a heavy container to accurately weigh in as many components as you want. Or that you can weigh one time on a lightweight paper, the next time into a heavy recipient; both times with results that are readable to the second decimal place.
To learn more about the many things your Mettler PC balance can do for you with outstanding speed and precision, send for our detailed brochure. It's an eye-opener.

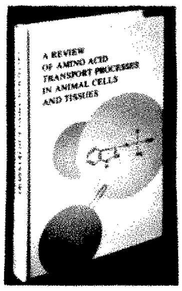
A Review of Amino Acid Transport Processes in Animal Cells and Tissues

Joseph Lerner



The only comprehensive, detailed study of the current status of organ and tissue absorption of amino acids in a wide variety of organisms. Separate chapters are devoted to the latest developments in regulation and adaptation in transport processes, transport mechanisms, ion dependency of transport, sugar-amino acid interactions, transport during development, effects of hormones, cyclic nucleotides, starvation and dietary deficiencies on transport, osmotic function of amino acids, disorders of transport and the relationship between active transport of amino acids and their incorporation into protein. An invaluable and unique resource.

Contents:

Organ and Tissue Absorption of Amino Acids • Transport in Parasites • Transport in Marine Organisms • Ion Dependency of Transport • Ideas in Transport Mechanisms • Sugar-amino Acid Interactions • Regulation and Adaptation in Transport Processes • Transport During Development • Effects of Hormones and Cyclic Nucleotides on Transport • Effects of Starvation and Dietary Dependencies on Transport • Relationship Between Active Transport of Amino Acids and Their Incorporation into Protein • Osmotic Functions of Amino Acids • Amino Acid Transport and the Mechanism of Insulin Release • Miscellaneous Effectors of Transport • Disorders of Transport • Glossary of Transport and Associated Terminology • Kinetic Symbols • Suggested Reading List • References • Index

234 pages, glossary, index, 947 references

J2017

Circle No. 08 on Reader Enquiry Card.

Cavendish Laboratory of Cambridge University which he visited in May of 1952, where John Kendrew asked him to speak with "two people who were trying to do something with nucleic acids". What happened:

> "The first impression was indeed far from favorable; and it was not improved by the many farcical elements that enlivened the ensuing conversation, if that is the correct description of what was in parts a staccato harangue . . . The impression: one, thirty-five years old; the looks of a fading racing tout, something out of Hogarth ('The Rake's Progress'); Cruikshank, Daumier; an incessant falsetto, with occasional nuggets glittering in the turbid stream of prattle. The other, quite undeveloped at twenty-three, a grin, more sly than sheepish; saying little, nothing of consequence; a gawky young figure, so reminiscent of one of the apprentice cobblers out of Nestroy's *Lumpazivagabundus*. I recognized a variety act, with the two partners at that time showing excellent teamwork, although in later years helical duplicity diminished considerably. The repertory was, however, unexpected. So far as I could make out, they wanted, unencumbered by any knowledge of the chemistry involved, to fit DNA into a helix."

In the case of Crick, this unencumbrance apparently persisted for some time, for as late as 1966 (*J. molec. Biol.* **19**, 548) we find him giving a drawing of a G–A pair featured by a non-bonded H · · · H distance between the bases of less than 1.7Å, a value impossibly small and ridiculously erroneous.

And then:

> "I told them all I knew. If they had heard before about the pairing rules [*sic*], they concealed it. But as they did not seem to know much about anything, I was not unduly surprised . . . I believe that the double-stranded model of DNA came about as a consequence of our conversation."

Now, there are only a very few people who are in a position to know whether or not this belief of his is true. I am one of them. I categorically state that it simply is *not* true. Shortly afterward, when I came on the scene, at such times as they were thinking about DNA, they worried more about the density, the pitch of the helix; pairing, if it came up, was "like with like", not complimentarity. They were not, in fact, even using the correct chemical structures of the bases. When the final model of DNA was discovered—more or less by accident—it wasn't Chargaff's rules that made the model, but the model that made the rules.

Finally:

> "Later, when molecular prestidigitation ran wild, I was often asked by more or less well-meaning people why I had not discovered the celebrated model. My answer has always been that I was too dumb, but that, if Rosalind Franklin and I could have collaborated, we might have come up with something of the sort in one or two years."

Crick's own estimate of how long it would have taken Franklin (by herself) to arrive at a correct structure is:

> "Perhaps three weeks. Three months is likelier. I'd certainly say three months, but of course that's a guess" [see *Rosalind Franklin and DNA*, by Anne Sayre, Norton, New York, 1975, p214].

This crystal balling, whether by Crick or Chargaff, to estimate the time required for the successful solution of a research problem is of course totally fatuous. Chargaff's estimate of two years, however, may safely be expanded to "never", because as late as 1952 he was referring to "enolic hydroxyls" (*Biochim. biophys. Acta* **9**, 399; 402). As everyone now knows, the Watson-Crick breakthrough is based on the fact that someone told them that there are *no* enolic hydroxyls in DNA, and had Chargaff used them an acceptable structure would never have been attained by him.

Some years previous to the "discovery of the century" Chargaff tells us that he "was in love with topology, and all forms of twisted rings filled the office. . ." and that "DNA was pictured as a Möbius strip." He then proceeds to give a wholly erroneous method for constructing such a strip. The love affair was obviously one-sided.

On science and research in our time

> "I would say that most of the great scientists of the past could not have arisen, that, in fact, most sciences could not have been founded, if the present utility-drunk and goal-directed attitude had prevailed".
>
> "Our kind of science has become so dependent on public support that nobody seems to be able to do any research without a handout. If their applications are turned down, even the youngest and most vigorous assistant professors stop all work and spend the rest of their miserable days writing more applications. This continual turning off and on of the financial faucets produces Pavlovian effects and a general neurasthenia that are bound to damage science irreversibly".
>
> "One man or two may decide to study a certain beetle. Whether they do this because the animal is a pest or a biological delight is immaterial. If they find something of scientific interest, there will soon be ten others and more who will do the same. Once there are a hundred men studying the beetle, they will form a society and publish a journal. A society creates a profession, and a profession cannot be permitted to die. It is up to the nation to support it. If the nation can be persuaded, there will soon be a thousand members of the society for the study of the beetle. It is obvious that at this stage the beetle can no longer become extinct, for what would all these experts do who may well outnumber the beetle? Then a foundation will arise whose lay members—influential bankers, society ladies—will neither know nor care whether their function is to help with the eradication or the preservation of the beetles. They know one thing: they must support those who study the beetle. There may even be a Beetle Ball. But what if the beetle disappears after all? The National Infantile Paralysis Foundation has avoided the worst by finally omitting its objective from its name. The American Cancer Foundation may find this more difficult".

Sic Transit

The penultimate section is entitled, *Liber Scriptus Proferetur*, and consists of a dialogue between the author and a "Voiceless Voice". It is a kind of *Höre mit Sinn, was ich dir sage*, and there is much said and much to listen to, mostly depressingly pessimistic, with the twilight glow gradually fading in the dim distance. Perchance the author is indeed a *Greis*.

Even though it may seem that I have some reservations, these, too, fade, with repeated reading of this book. Read it yourself, by all means. It is readable, enjoyable, enlightening, and at times hilarious without being funny. In the spectrum of scientific autobiographies which runs from the unbelievably dull to the delightfully enthralling, Chargaff's shines near the top. ☐

Jerry Donohue is Rhodes–Thompson Professor of Chemistry in the University of Pennsylvania. He spent the academic year 1952–53 as a Guggenheim Fellow at the Cavendish Laboratory, University of Cambridge, UK.

Thirties science movement

Steven Rose

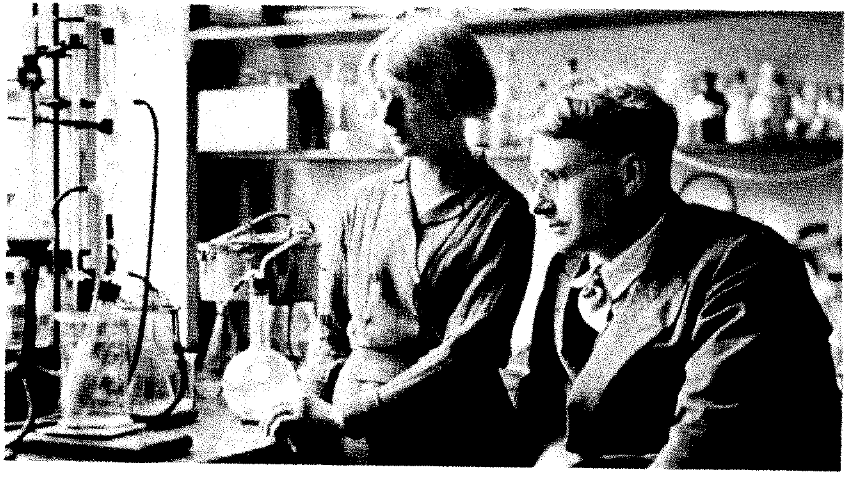
The Visible College: A Collective Biography of British Scientists and Socialists of the 1930s. By Gary Werskey. Pp. 368. (Allen Lane: London, 1978.) (Publication date: 16 November.) £10.

In the history of science as an institution, from the first tentative steps towards the organising of like-minded amateurs in the seventeenth century, to its present-day well-nigh total incorporation into the machinery of the state, the period between the 1914–18 and 1939–45 Wars occupies a position of particular interest and importance. For countries like Britain the Great War demonstrated the need for more decisive state and industrial intervention into the course of science and resulted in the establishment of forms of organisation—such as the Research Councils and Associations—which have remained with us through all the exponential growth phase of science spending which followed, until the present day. This expansion in the scale of scientific effort and rate of scientific advance (limited though it was by the depression of the 1930s), had a series of consequences.

An increase in the number of professional and qualified scientists and engineers and the resultant modification in their work style and class perspectives resulted in the first moves towards scientific unionisation with the National Union (later Association) of Scientific Workers, today merely a nostalgic memory in the maw of Mr Clive Jenkins' Association of Scientific, Technical and Managerial Staffs (ASTMS). In the superstructural world of the intellectuals science could no longer, as it had previously, be regarded with Swiftian or Peackockeian disdain by the literati; what scientists said and thought about the world began to matter: *par excellence* this was the period of Snow's Two Cultures.

By the end of the 1939–45 war and the years that followed, the scientisation of everything had changed the terrain of that battle beyond recognition. As a result of these developments, particularly in the cataclysmic decade of the 1930s, science could no longer remain disengaged from politics at any level. What science was financed, and how, was a political question; what science discovered, and how it proceeded, were political and ideological questions; what scientists said—about science and about politics—began to matter in a way that had never been the case before.

These changes excited, engaged, divided the 'scientific community'—by which one normally means that visible part of the profession which is university-based and regards it as its role to provide intellectual leadership. The divisions transcended academic debates and spilled out even from the pages of *Nature* into popular writings and political organisations. On the one hand there was a combination of mystically minded idealists like Jeans and Eddington, traditional conservatives with a dislike for the radical changes that were beginning to show in the scientific profession, like A. V. Hill, and proselytysers for a romantically conceived 'freedom' in the 'republic of science' like Baker and Polanyi. On the other, a formidable group of intellectuals with a range of talents within their disciplines and political and organisational skills that were to play their part in the total transformation of science in the decade that followed—Bernal, Haldane, Hogben, Levy, the Needhams, the Fremlins, the Piries, the Woosters, aided by a new species of science writers with access to the daily press like Crowther and Ritchie Calder.



Dorothy & Joseph Needham in 1927 at the Dunn Biochemistry Institute, Cambridge

The history of the science movement of this period is central to an understanding not merely of the political and cultural ferment of the 1930s, but to the appreciation of the intellectual and organisational origins both of British state science policy as it developed in the post-1945 period and of the new radical science movement which emerged in the 1960s. It is both surprising and slightly embarrassing that, although studies of the literary intellectuals of the 1930s have been so common, we should have needed to wait so long for the history which Gary Werskey has attempted in *The Visible College*.

Werskey's book has grown out of the thesis he embarked upon more than a decade ago now. His method is to analyse what we would today call the radical science movement, then referred to as the 'social relations' or 'social functions' of science movement, through a discussion of the activities and careers of five key figures; Bernal, Haldane, Hogben, Levy and Joseph Needham. He briefly traces the biography of each before the 1930s, trying to identify those factors in their development which led them eventually to socialism and for several, membership of the Communist Party. For Werskey's analysis the intellectual pivot around which the book revolves was the now famous International Congress of the History of Science in London in 1931, to which the Russians sent a highpowered delegation headed by the major theoretician and Old Bolshevik Bukharin, which transformed the younger British scientists' understanding of the social processes of science by presenting them with a worked-out analysis of the historical and economic determinants of Newton's *Principia* as rooted in the needs of the emergent English bourgeoisie of the seventeenth century. The externalist analysis of the history of science was born.

In two central chapters Werskey discusses first the theoretical issues for the left scientists—essentially disparate attempts to define the relationships of science to dialectical materialism (particularly Haldane) and the social functions of science (Bernal)—and second, their practical work in the Association of Scientific Workers and, later, the Cambridge Scientists' Anti-War Movement. There is a brief account of the War and post-War years—disappointingly thin compared with the wealth of published autobiographical material available here—and a concluding chapter significantly entitled "Coming in from the Cold". Finally, an afterword very briefly summarises the heritage of the movement in the Janus-form of the almost total acceptance of state planning for science in

Techniques of Chemistry Vol. 12: Separation and Purification 3rd Ed.
Series Editor: **Arnold Weissberger**; Volume Editor: **E.S. Perry**, *Eastman Kodak Co., Rochester, New York.*
This provides the theoretical background for an understanding of the various methods and operations, and describes the techniques and tools, their ,modifications, merits and limitations, and their handling.
October 1978 452 pages
0471 02655 7 $43.00/£21.50

The Carbon-Carbon Triple Bond
edited by **S. Patai**, *The Hebrew Institute, Jerusalem.*
The series, "The Chemistry of Functional Groups" is planned to cover in each volume all aspects of the chemistry of one of the important functional groups in organic chemistry, in this case the compounds containing a carbon-carbon triple bond. The emphasis is laid on the functional group treated and on the effects which it exerts on the chemical and physical properties, primarily in the immediate vicinity of the group in question and secondly on the behaviour of the whole molecule. The authors concentrate on important developments and on material which has not been well covered in other literature. (Series: *The Chemistry of Functional Groups)*
September 1978 536 pages
0471 99497 9 (part 1) $70.00/£35.00

Megawatt Infrared Laser Chemistry
by **E. Grunwald** and **P.M. Keehn**,
both of *Brandeis University, Massachusetts,*
and **D.F. Dever**, *Macon Junior College.*
An introduction and a reference to the rapidly developing field of infrared laser chemistry. The authors describe and explain all aspects of the field — adsorption of infrared radiation from laser sources; energy-flow patterns within the absorbing molecules; the economics, controllability, and scope of laser-induced reactions. Established facts and theories are covered along with the basic issues of that branch of chemistry involved with pulsed infrared lasers at megawatt per centimeter power levels — currently the most important area of concern to chemists.
October 1978 122 pages
0471 03074 0 $21.50/£10.60

The Chemistry of Our Environment
by **R.A. Horne**, *Arthur D. Little, Inc.*
Describes the major environmental domains, exosphere, atmosphere, hydrosphere, lithosphere, and biosphere, and their interacting chemical relationships. Discusses chemical alteration and pollution of the environment as well as "internal pollution" caused by drugs and food additives. Treats each topic within the relative significance of anthropogenic and "natural" pollutant sources.
May 1978 882 pages
0471 40944 8 $36.70/£19.40

Brain Systems and Psychological Concepts
by **J. Boddy**, *Department of Psychology, University of Manchester.*
The emphasis of this textbook of physiological psychology is on the way brain systems mediate consciousness and behaviour. The author has tried to achieve a better integration of psychological and physiological data than has previously been available; the necessary basic concepts of neural structure and processes have been kept brief and concise to allow the behavioural implications of central neural systems to be dealt with in some depth.
September 1978 478 pages
0471 99601 7 (cloth) $27.50/£12.50
0471 99600 9 (paper) $14.00/£5.95

Biology Teachers' Handbook 3rd Ed.
Biological Sciences Curriculum Study (BSCS)
A new and revised edition of one of the most useful instructional tools for teachers of secondary and tertiary introductory biology. It provides a step-by-step guide to the enquiry method, introducing "Invitations to Enquiry" — a unique learning device designed to help teach students more effectively.
October 1978 604 pages
0471 01945 3 $19.75/£10.80

World Communication: Threat or Promise? (Revised Edition)
by **C. Cherry**, *Department of Electrical Engineering, Imperial College, London.*
This book, which attacks many popular beliefs about communication, examines the influence of technological developments upon international relations — more especially the very rapidly expanding global communication network. It first examines the nature of human communication, regarding it as a 'sharing' process (not merely the sending of messages) and it then considers the constraints of various technological systems, for example the international telephone system. It deals with the organisation of world communication (as a political activity) and some of its history.
July 1978 244 pages
0471 99616 5 (cloth) $23.30/£11.00
0471 99660 2 (paper) $9.50/£4.75

The Reward System in British and American Science
by **J. Gaston**, *Southern Illinois University.*
Attempts to determine whether scientists' reputations can be attributed to research productivity or to the social connections they have acquired. Using a randomly selected, representative sample of physicists, chemists, and biologists from the United States and Britain it examines how each country's social organization of research affects the way its reward system operates. Previous research is assessed and current views modified to provide solutions to many previous concerns while raising additional questions. *(Science, Culture, and Society Series)*

ATLAS OF SPECIATION IN AFRICAN NON-PASSERINE BIRDS
Edited by D. W. Snow

This is a companion volume to the *Atlas of Speciation in African Passerine Birds*, by B. P. Hall and R. E. Moreau (1970); together they represent the first attempt at a detailed mapping of a major continental avifauna. It is a composite work, with contributions by 13 authors from six countries. 1978 349mm x 251mm 392 pages 391 maps in two colours.

ISBN 0 565 00787 4 **£42.50**

THE YORKSHIRE JURASSIC FLORA, Volume V. CONIFERALES
T. M. Harris

This is the final volume of this important series, it is expected to appear in print in early 1979.

May be ordered now. **The price will be about £35.00**

AN ENUMERATION OF THE FLOWERING PLANTS OF NEPAL, Volume 1. THE MONOCOTYLEDONS
H. Hara, W. T. Stearn & L. H. J. Williams

This work, to appear in three volumes, is a joint project of the British Museum (Natural History) and the University of Tokyo. It is based on the extensive botanical exploration of Nepal by British and Japanese scientists during the last 25 years. The systematic text is preceded by chapters covering the floristic exploration in Nepal, an outline of the geography of the country and the considerable horticultural interest of its flora. The manuscript of Volumes 2 and 3, covering the Dicotyledons, is well advanced, and publication can be expected within 2 years.
1978 soft covers 215 x 275mm 154 pages 7 figs

ISBN 0 565 00777 7 **£22.50**

REPORT ON THE BRITISH MUSEUM (NATURAL HISTORY) 1975-1977

The fifth triennial report published by the Museum since the administrative connection with the British Museum was severed in 1963. Besides documenting the Museum's many activities, the Report includes twelve original articles by members of the scientific staff dealing in greater depth with selected topics.

a capitalist Britain, and the rebirth of the radical science movement in the late 1960s around the issues of chemical and biological warfare and later the founding of the British Society for Social Responsibility in Science. Here, where my generation's autobiographies begin to interlock with those of the 1930s movement, Werskey leaves his story.

One should not underestimate the importance, or the difficulty, of the task Werskey sets himself. But I believe that in the last analysis he fails, and that the reasons for this failure are not uninstructive.

Firstly, the book is very uneven. It changes style and method as it progresses—the inevitable consequence perhaps of an overlong gestation period, and one during which the author's own political and intellectual positions *vis-à-vis* his protagonists and their goals have themselves undergone a considerable evolution—as he himself would, I am sure, be the first to agree. Thus, we move from a sort of psychologising biographical enquiry, seeking to root the socialism of Bernal and his colleagues in their early childhood, to an intellectual debate with the theoretical postulates of dialectical materialism as they were interpreted during the 1930s, to an account of a social movement and a puzzled attempt to come to terms with why left intellectuals in the 1930s saw the Communist Party as the proper and inevitable place to be.

Hyman Levy broadcasting a science programme for the BBC in the 1930s

Haldane attempting to stir up a 'United Front' meeting in Trafalgar Square in 1937

The book is at its strongest when it discusses social movements like the Cambridge Scientists' Anti-War Movement. Elsewhere, it falters. It would be wrong to argue that only an insider could have written the history that Werskey has attempted, although it is true that a certain unease about the young American historian of science amongst the potential subjects of his enquiry has limited his access to some of the most interesting documentary material of the period, but nonetheless a consistent method of approach and a more basic sympathy with the intellectual as well as the social tasks that the Social Functions of Science movement attempted would have avoided some of Werskey's problems. If he had based his analysis on the changing objective status of British science *vis-à-vis* British society he would not have been forced back into the sort of psychologising that wants to seek common features in the marginality of his key figures (to argue that Haldane's Scottish connections made one who was so solidly born into the British scientific and political aristocracy and Oxford society 'marginal' is surely stretching a point). His account of the Cambridge social scene of the 1930s is too uncomfortably reminiscent of Jim Watson's 1950s version in *The Double Helix* to carry total conviction. His essential unconcern for the scientific problems which Haldane, Bernal, Hogben, Levy and Needham set themselves also leaves him unable to see the importance that they felt holistic methods opened up within their own subject areas, by contrast with either mechanical reductionism on the one hand or idealism of the Mach/Jeans/Eddington type on the other. Yet much of their best theoretical writing, and that of their colleagues and followers was addressed to just these questions. The analysis of the social functions of science was merely one aspect of the challenge that the left scientists presented; the issues and approaches that they opened in theoretical, population, developmental and human biology remain a profound and to date inadequately discussed theme (partly, it is true, due to the tendency of Haldane to mask subtle truths in outrageous *obiter dicta* and of Bernal to subordinate many of his theoretical concerns to those of the intellectual defence of the Soviet Union even where it was indefensible); nonetheless Werskey largely ignores this aspect of the group's work.

A further problem to Werskey is the role of the Communist Party and the relationship of his subjects to it. Again this problem partly derives from the technique of the tracing of five interlinked careers rather than the social movement and its objective base; he thus has to look for individual motivations rather than changing social and economic circumstances. But also, one feels that Werskey has not been able to shake himself entirely free from a cultural and political background in which the American cold-war assumptions of his early training was followed by the essentially spontaneist radicalisation of the student movement of the 1960s. For him therefore, the Communist Party always appears as an external force motivated by Moscow, involved in Machiavellian schemes to control, neutralise or otherwise manipulate the misguided intellectuals. This is apparent in his choice of language; he speaks of Bernal and his "cohorts", a "left wing coterie" and so forth. Nor is his overall grasp of international communist theory and politics in the 1930s and 1940s absolutely sure, even on issues impinging directly on the science movement—for instance one should not argue that Stalin made a "sudden decision" in July 1948 to put T. D. Lysenko in charge of Soviet biology, especially after the re-analysis of the Lysenko affair in recent years by Lewontin and Levins, and by Lecourt.

What is of real interest is the essentially progressivist image of science that the old left had: science was inevitably in contradiction with capitalism and on the side of socialism. This was a view shared—and indeed Werskey hints at this—by the Communist Party with its belief in the 'scientific' nature of its version of Marxist theory. The alliance between socialist scientists and the Communist Party was thus inevitable. Indeed, it was a great deal more durable than that between non-scientific intellectuals in the 1930s and radical or Communist politics. The interesting point is the importance both sides attached to this alliance—for instance, natural scientists formed a significant segment of the Editorial Boards of the main theoretical journals of the Party and non-Party left in the 1930s and 1940s.

One of the most important differences between them and us is that the organised left no longer lays claims to such people; today its theoreticians are sociologists rather than scientists. Few of the leading cadres of the new radical science movement in Britain are active in scientific research in the same way as was the generation of the 1930s. The reasons for this change are surely connected with a completion of those tendencies in the development of the social functions of science which the 1930s heralded.

While Werskey's book remains the only history of the 1930s science movement, this analysis will, however, remain incomplete. ☐

Steven Rose is Professor of Biology at the Open University, Milton Keynes, UK.

Shades of Audubon

C. M. Perrins

Audubon: A Biography. By John Chancellor. Pp. 224. (Weidenfeld and Nicolson: London, 1978.) £6.95.

LAST year, an original set of Audubon's plates *The Birds of America* was sold at auction for a little over £200,000, the highest price ever paid for a copy of a printed colour-plate book. These extended-coffee-table works have captured the imagination of the world and a number of biographies have already been published. One therefore picks up another biography of Audubon with a little caution. The work under review, however, is a useful history of this man. It traces his family history and his early life in detail, following him through the period when he struggled to make a name for himself to his later life when he was already "a legend in his time."

Audubon was born in 1785, an illegitimate son of a French sea-going father. His mother is of uncertain history; she was called a "creole", but at that time this could have meant a number of things, from half-caste to a person whose family had lived in Latin America for several generations. The family background was one of the slave-owning communities of the southern states and Caribbean; indeed Audubon's father was for a time a slave trader himself. The father and two children returned to France at the time of the French Revolution and the young Audubon was brought up, largely by a stepmother, during these difficult times. He did not return to the New World until the age of 28. By this time he was already a dedicated naturalist and was drawing birds. Once in the States, he devoted his time to hunting, shooting and drawing to the extent that his business ventures failed with dismal reliability. He tried to run a number of merchant stores, moving westwards to Kentucky.

Always he hunted, painted and drew. In the early years he did not do so with any clear plan in mind for publication. However, such a thought may have been sown at a meeting with Alexander Wilson in 1810. Wilson, the first man to publish a book of coloured illustrations of American birds, approached Audubon to seek a subscription for his work (to be published as a serial). Nevertheless, another decade and a half were to pass before Audubon tried seriously to follow suit. During this time his business ventures continued to fail and he and his family were often destitute. Although Audubon sometimes made ends meet by drawing and painting portraits, he never made much money from his natural history work. His wife, Lucy, whose marriage settlement he had long since spent, was often the mainstay of the family, earning a living as a teacher while her husband disappeared into the bush on hunting trips.

Things changed at last in 1826 when Audubon arrived in Liverpool and started to display his paintings in earnest. He met many enthusiastic subscribers for his proposed work and, after finding a publisher who was capable of doing the difficult work of preparing the plates (an Edinburgh firm failed in the early stages and most of the work was engraved by the London firm of Havell) things never really looked back. True, from time to time the number of subscribers dropped (at one time 50 of the 180 subscribers failed to renew their support) because Audubon was wandering in search of further birds and not trying to maintain or increase the number of subscribers; but he was never really short of funds again. By 1831, at the age of 46, Audubon returned to the United States a celebrity. In all *The Birds of America* comprised 87 parts, each of 5 plates—435 plates figuring 489 species. The first part appeared in 1827, the final one in 1838.

Audubon continued to visit England where he had a son overseeing the production of his work at Havell's. He continued to undertake expeditions searching for more species and he started new projects, including the production of an octavo edition of his *The Birds of America* (1840–44), his journals (*Ornithological Biography*, 1831–39), and *The Viviparous Quadrupeds of North America* (1845–48). Many of these were undertaken with assistance of others. The text for his main work and for his journals was heavily re-written by the Scotsman William MacGillivray, himself author of an important work *A History of British Birds*; the text for *Quadrupeds* was written by the Rev. John Bachman, a long-time friend. Audubon died in 1851 before the completion of a new version of this work.

Barn Owls

Plate CLXXI of *Birds of America*

Painting of Audubon by his son

All this has been said a number of times in the numerous biographies. However, the work reviewed here does perhaps stand apart from some of the previous works which have tended to idolise Audubon. John Chancellor is more inclined to be openly critical of parts of Audubon's life. The artist made many enemies during his life and not without cause. He must at times have been an exceedingly difficult person to put up with. He was indolent and unfaithful to his trading partners. He treated his family badly. Even when he was becoming established as an artist he had little loyalty to many of his aides. The backgrounds for his artwork were usually done by other artists; they seldom got much credit and sometimes their names were deleted from the plates. His journals are contradictory and, to put it as politely as possible, Audubon tended to over-embellish the happenings on his journeys. He tried to put himself across as a colourful woodsman. Although it is not really fair to criticise Audubon for lack of conservation interests, as the idea of conservation barely existed at that time, he was wildly trigger-happy. A place where he shot fewer than 100 birds in the course of a day was rated "very poor for birds". It is a little wry

New and Forthcoming Titles

HUMAN BEHAVIOUR AND ADAPTATION

Edited by V. Reynolds and N. Blurton-Jones

Vol 18, Symposia of the Society for the Study of Human Biology.

Part I focuses on the long-term evolutionary aspects of human adaptation in relation to behaviour and culture, Part II on short-term adjustments of the individual in his everyday life in a given environment. New research results and discussions are presented.

312pp 216 × 138mm £12.00
Cloth 0 85066 137 4 October 1978

PHYSICS TEACHING IN SCHOOLS

Edited by G. Delacôte

Proceedings of the 5th biennial GIREP seminar.

The principal themes of this book are 'Statistics and probability in the teaching of physics in the secondary school' and 'First steps in the teaching of physics at the beginning of secondary school (10-14 years)'. Plenary lectures and shorter communications are presented followed by summaries from the Working Groups.

350pp 240 × 174mm £20.00
Paper 0 85066 136 6 October 1978

PRODUCTION AND INDUSTRIAL SYSTEMS

Edited by R. Muramatsu and N. A. Dudley

The 4th International Conference on Production Research took place in Tokyo in August 1977, taking as its theme the applications of industrial engineering to all facets of manufacturing. Ninety-six of the papers presented are contained in this volume.

1300pp 250 × 176mm £52.00
Cloth 0 85066 138 2 November 1978

MY LIFE

Recollections of a Nobel Laureate

Max Born

In this book of informal recollections—originally intended for his family—one of the great scientists of our time has written a rich and vivid account of his life and work, including life in Germany and as a member of the Jewish community around the turn of the century. The developments in science as well as politics can be followed.

312pp 240 × 174mm £8.50

Would a bite of potato taste like potato or onion if an onion were held under the nose at the time?
(Answer below)

OLFACTION AND TASTE VI
Edited by: J. Le Magnen P. MacLeod

The Proceedings of the Sixth International Symposium on Olfaction and Taste, held at Gif-sur-Yvette, Paris, France, 15-17 July, 1977, have been published by IRL. The book consists of the forty-five eight-page papers and the abstracts of the ninety-five poster presentations given at the conference.
The material covers the latest research on the molecular properties responsible for taste and odour, the "recognition" of these molecules by receptor cells and the function of the neural pathways involved. It includes investigations of secretory products of the olfactory epithelium, discrimination of mixed stimuli, hormone regulation of olfactory stimuli and the resultant effect on animal physiology and social behaviour.
The book is published in hard back and contains full Author and Subject Indexes and a list of the participants.
500 pages £15.00/US $25.00

that a man who shot anything and everything should have given his name to the greatest conservation organisation of our time. On the credit side, his field observations were accurate compared with other contemporary works.

I would have preferred the author to say rather more about the artwork itself. As with the other aspects of Audubon's life, it has both admirers and detractors. Again, it is necessary to set the artwork in its time. There was very little else and what there was was stilted and un-natural, a point that Audubon was quick to stress. Not that, to the reviewer, many of Audubon's own paintings are of great merit in this respect. Many of the birds are depicted in grotesque attitudes which they could never achieve in life; this is especially true of the larger birds whose necks he bent into odd shapes to get them on the page. Perhaps the single most effective aspect of the artist's work was to draw the birds on so grand a scale, the enormous elephant-folio size contributes to the impact of the plates.

The work reviewed here is profusely illustrated. Many of the illustrations are not drawings of Audubon's but works by other artists depicting, for example, places which he visited. Sadly many, presumably for reasons of cost, are monochrome not colour. In fact there are only nine colour reproductions of Audubon's bird work and two of his mammals. The reviewer would have welcomed slightly more detailed documentation and a larger bibliography. Nonetheless, the book makes interesting reading and will be appreciated by many who admire the artist's work and wish to learn more about him. The author has produced a thoroughly readable and attractively produced book. ☐

C. M. Perrins is Director of the Edward Grey Institute of Field Ornithology, University of Oxford, UK.

Anecdotal history of Kew Gardens

William T. Stearn

In for a Penny. A Prospect of Kew Gardens: Their Flora, Fauna and Falballas. By Wilfrid Blunt. Pp. 218. (Hamish Hamilton and Tryon Gallery: London, 1978). £7.95.

WILFRID BLUNT is a master of anecdotal history and biography, as his works on such diverse characters as Sidney Cockerell, King Ludwig of Bavaria, Carl Linnaeus, Felix Mendelssohn, John Christie and G. F. Watts testify. In the Royal Botanic Gardens, Kew, he has found yet another subject for his witty light-hearted versatile scholarship and an approach which he correctly and disarmingly describes as "personal, capricious, irreverent" and "perhaps even prejudiced, for I have always had a kind of love–hate relationship with the botanists". His book is an entertaining combination of guide-book and history, well written and profusely illustrated.

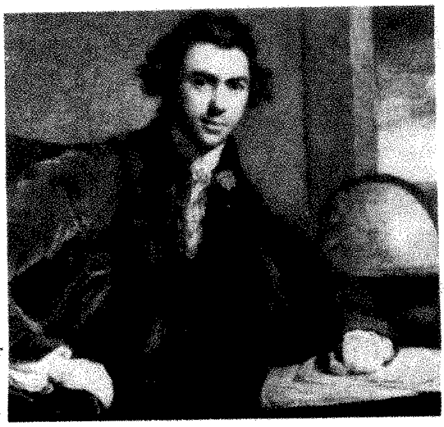
As a botanic garden, Kew, although the mother of gardens in many parts of the world, seems young by comparison with the botanic gardens of Oxford (founded in 1621) and Chelsea (founded in 1673) and even more so with those of Pisa (founded in 1543) and Padua (founded in 1545). All these had originally a medicinal and teaching intent. Kew, which goes back as a botanic garden no further than 1760, owed its existence less altruistically to royal pleasure, beginning with Queen Caroline, wife of George II, whose pet poet and tame hermit Stephen Duck (1705–56) has provided Blunt with material for an amusing marginally relevant chapter.

The horticultural zeal of Frederick, Prince of Wales, and his Princess, Augusta, determined the future of their royal Kew estate. Without them it could never have become the world's finest botanic gardens. In 1959 the Royal Botanic Gardens celebrated the engagement of a Scottish head gardener, William Aiton, as the founding of Augusta's Kew botanic garden, although Sir William Chambers, her architect, writing in 1763, had stated that the "Physic or Exotic Garden was not begun before the year 1760". Between 1757 and 1762 Chambers embellished the Kew park with a diversity of structures, of which the orangery and the pagoda stand as his most conspicuous monuments. Augusta's botanic garden occupied some nine acres of the present 300 acres forming the Royal Botanic Gardens. Blunt's first five chapters deal with this Hanoverian period and he joyfully incorporates its scandalous rumours about an affair between Augusta and her horticultural and botanical adviser, Lord Bute.

Augusta died in 1772. Under her son, George III, Sir Joseph Banks (1748–1820) took control of Kew, sent collectors far afield to enrich it with new plants and employed his botanist-librarians, Solander, Dryander and Robert Brown, to classify and name them and an artist of genius, Franz Bauer, to paint them. The result of their endeavours was the *Hortus Kewensis* published as the work of W. Aiton and his son W. T. Aiton, "the names of native dunces being suffered to usurp the place belonging to those of the genius and talent of another land", according to Ker-Gawler in 1823. (The specimens on which this monumental work was based are in the British Museum (Natural History), not Kew.)

Banks gave the Kew garden an international repute. Unfortunately, as Blunt says, "after the death of Banks in 1820 Kew entered upon the two darkest decades of its history. Indeed it sank so low that at one time what Augusta and Bute had so lovingly created, what Banks had so skilfully nurtured, seemed about to decline into kitchen gardens to provide cabbages for Kings" and might have ended as a built-up area.

The crisis came in 1838. Few of the many visitors to the garden and few of the research workers in the herbarium, libraries and laboratory know that, but for the efforts of a few influential and far-sighted men in the years 1838–42, they would have no Royal Botanic Gardens, Kew, today. The gardens were then under the control of the Department of the Land Steward, who was the Earl of Surrey, and the government, which would have been glad to be rid of them, set up a committee of enquiry for the purpose. It included the Earl of Surrey's head gardener but he was an ineffectual counterweight to Professor John Lindley, a man not only of great botanical knowledge and horticultural experience but also of forceful character, forthright speech and a vigorous lucid style, and Joseph Paxton, the Duke of Devonshire's head gardener, likewise a man of independent views. Lindley's report, advocating the conversion of the gardens into a public institution for promoting botanical science, was not what the government and young Queen Victoria wanted. Public indignation at the proposed destruction, however, led to the adoption of Lindley's views on the function and future of Kew, and in



Sir Joseph Banks

Joshua Reynolds, about 1773

Sir William Hooker

Linnaen Society, London

1841 William Jackson Hooker came from Glasgow to be the director of the Royal Botanic Gardens, which under his guidance then developed into the botanical centre of the expanding British empire, as Lindley had hoped. I think Blunt does not give Lindley enough credit for his major contribution to the saving and development of Kew.

That development makes a varied story. Blunt tells it in fragments as he conducts his readers on a tour of the Marianne North Gallery, the Cambridge Cottage, the T-Range, the Herbarium and so on, though failing to do more than view from a distance the Jodrell Laboratory, which is a pity, as its forensic associations alone would have given him interesting material. Moreover, here C. F. Cross and E. T. Bevan did the early work leading to their discovery of viscose in 1892 and so to the rayon manufacturing industry. The celebrated plant anatomist and palaeobotanist, D. H. Scott, Honorary Keeper of the Jodrell Laboratory from 1892 to 1906, is likewise nowhere mentioned. Thus, although Blunt provides an excellent general view of Kew as a visitor sees it, together with a good historical background, the scientific work done there is largely and deliberately outside his chosen field. Indeed he describes his book as "an aperitif to the feast that Kew provides, not a meal to be consumed in the gardens."

Blunt asks "my friends the botanists to forgive a little gentle badinage at their expense". They are, he says, "kind and delightful people"; he should therefore have asked more of their help over his shaky acquaintance with plant names. Thus, he attributes the coinage of the old Greek herbgatherer's name ὀρχισ (testicles) to Theophrastus, who simply used the common vernacular names of his times. "Why", he asks, "did they [the botanists] make Orchis *feminine* when the Greek word, and what it stands for, are masculine?". In fact modern botanists merely follow classical usage. The Ancients when using the word *orchis* not literally for humans but metaphorically for plants made it feminine in gender because most of their plant names were feminine and an association with a feminine noun such as ἐλαια (olive), *olea* or *herba* was implied. Thus Pliny wrote "mirabilis est orchis herba sive serapias, gemina radice testiculi simili." As regards the names of multigeneric orchid hybrid groups (see p177), the proposal to name these by attaching the termination *-ara* to the surname of a person was devised by E. A. Bowles about 1909, and put forward at the Brussels Botanical Congress of 1910, by which time such unwieldy condensed formulae as *X Brassocatlaelia* and *X Sophrolaelio cattleya* already existed. However, as Blunt says, "all of this has little or nothing to do with Kew".

It is unfortunate that he should repeat the old libel that work in the Kew Herbarium "adds to the misery of gardeners by constantly changing the scientific names of familiar plants". There is still room for a book covering the multifarious activities of Kew, which have included efforts to preserve unchanged the scientific names of plants. On p114 Kew and South Kensington are confused in a quotation from Beatrix Potter's diary; the entomologists Kirby and Waterhouse and the anatomist Sir William Flower were never members of "Kew's behind-the-scenes staff"; they worked in the British Museum (Natural History).

The illustrations delightfully supplement the text; one portrays the director Sir William Thiselton-Dyer, "whose sense of humour was limited though that of his self-importance was not", as Blunt observes, parading in a constable's uniform with his garden constables. William Purdom, the rebellious Westmorland gardener who defied the autocratic Sir William, subsequently became a plant collector in China for Messrs Veitch and the Arnold Arboretum and travelled with Reginald Farrer. Indeed the history of Kew teems with names illustrious in botany and gardening, as well as some notorious, and Blunt has gathered anecdotes about them from multitudinous sources to produce a lively "personal, capricious, irreverent" book. ☐

W. T. Stearn is a Visiting Professor in the Department of Botany, University of Reading. His continuous unofficial but close association with the Royal Botanic Gardens, Kew, began in 1930.

Crusade against malaria

L. J. Bruce-Chwatt

Mosquitos, Malaria and Man: A History of the Hostilities since 1880. By Gordon Harrison. Pp. 314. (John Murray: London, 1978.) £8.50.

THIS study by a "military and political historian and an environmentalist" (as stated in the author's preface) covers the period 1880–1976 of man's fight against malaria, the world's most prevalent tropical disease.

The book starts with the description of the discovery of the malaria parasite in Algeria by the French military surgeon Alphonse Laveran; it provides interesting and little known information on the background to this event and points out the difficulties that Laveran had in convincing the medical pundits (including William Osler) of the importance of his finding.

The next few chapters are devoted to Ronald Ross, undoubtedly the most colourful personality in the history of tropical medicine. Ross's "pilgrim's progress" from his first contact with Patrick Manson, through his fumbling, laborious and then inspired work in India, to the crowning glory of the Nobel Prize awarded for the discovery of the transmission of malaria by mosquitos, is told with much understanding and fluency.

Ross's bitter quarrel with the Italian investigators leads the author to an excellent appraisal of the major scientific contributions of Golgi, Grassi (Ross's "bête noire"), Dionisi, Bignami and Bastianelli. Here once again many interesting details, based on thorough research of original sources enliven the narrative. Robert Koch's little known and less than illustrious role at this stage of the history of malaria is discretely but skilfully reported. There follows the chapter on "three lives of the Plasmodium" which takes the reader through the explanation of the cycle of transmission of the human malaria parasites, including the cryptic tissue phase revealed in 1948 by Shortt and Garnham.

To introduce the concept of malaria control by the attack on the vector the author presents a sequence of events of the first quarter of this century, from Ronald Ross's first attempts at oiling

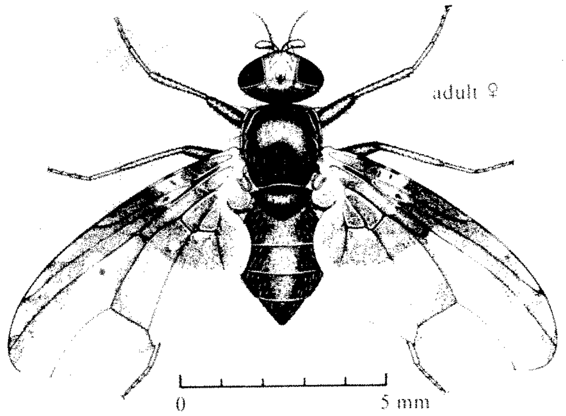
Paperback edition

Agricultural Insect Pests of the Tropics and their Control

DENNIS HILL



Ceratitis Coffeae (Bezzi)

Now available for the first time in paperback this important work that is both a textbook on insect and mite pests of tropical crops and a handbook for practising entomologists.

'... a very useful work of reference, a painstaking compilation of material from a wide range of sources which any applied entomologist interested in tropical pest control will want on his shelves. The author is to be congratulated on his contribution.' *Agro-Ecosystems*

Also available in hard covers **Paperback £6.95 net**

William Henry Bragg

1862-1942

Man and Scientist

G. M. CAROE

This biography of William Henry Bragg is written by his daughter for the general reader and tells the story of an eminent scientist who in 1915 shared a Nobel prize with his son William Lawrence Bragg for their work on the structure of crystals, using X-ray diffraction techniques.

'She (the author) has brought to life a big slice of those heady days when science – physics in particular – leapt forward into atomic structure, with X-rays and radioactivity, crystallography, J. J. Thomson, Einstein and Planck.' *The Economist*

£8.95 net

A Dictionary of Microbial Taxonomy

the late S. T. COWAN

Edited by L. R. HILL

This Dictionary started as a revision of *A Dictionary of Microbial Taxonomic Usage* (1968, Oliver & Boyd), but has been greatly enlarged and the scope widened. To make it generally useful, it includes words that may be met by general readers or by those seeking the usage of a word outside their disciplines. Some of the entries are short essays and throughout the volume the philosophical aspects are emphasised. The main aim of the Dictionary is as an accurate guide to taxonomic practice and it will be a standard work of reference.

Paperback edition

Models in Ecology

J. MAYNARD SMITH

This widely acclaimed book deals with ecological models of two kinds: mathematical models of a strategic kind, aimed at an understanding of the general properties of ecosystems, and laboratory models with the same aim in view. The author has concentrated on making clear the assumptions behind the mathematics and the conclusions to be drawn. The book is therefore comprehensible to those with a minimal familiarity with mathematical notation.

'This is an invaluable introduction for the would-be ecologist.' *The Naturalist*

Also available in hard covers **Paperback £2.95 net**

Man and Nature in the Renaissance

A. G. DEBUS

An integrated introduction to science and medicine from the mid-fifteenth to the mid-seventeenth century. The book is illustrated with many beautiful, contemporary pictures and is suitable for undergraduate students taking courses in the history of science, and for general readers with an interest in this fascinating field.

Cambridge History of Science Series

River Plants

The Macrophytic Vegetation of Watercourses

S. M. HASLAM

Rivers provide a fascinating and complex environment for plants. This book, intended for amateurs interested in rivers as well as for specialists, gives the first full-length account of river vegetation.

'... an outstanding single-handed contribution to river biology – the first classification in terms of their macrophytes of British (and some North American) watercourses. The book can confidently be recommended to all those interested in the ecology of freshwaters.' *Nature*

DIFFERENTIATION OF NORMAL AND NEOPLASTIC HEMATOPOIETIC CELLS

Edited by **Bayard Clarkson,** Memorial Sloan-Kettering Cancer Center
Paul A. Marks, Columbia University
James E. Till, Ontario Cancer Institute

A unique collection of exciting current research reports on the development of normal and neoplastic blood cells, this book provides the comprehensive and wide-ranging overview that has been sorely needed by research workers, students, and clinicians.

The diverse aspects of this topic are carefully considered with the emphasis on the interrelationships between them. Summaries by leading workers in each subtopic area provide the background needed to gain a perspective on the topic as a whole.

For cellular and molecular biologists, immunobiologists, and clinical investigators, at last a book with the scope to cover this topic of such unusually broad interest.

1978, 994 pp., CIP
LCN: 78-60391 ISBN: 0-87969-121-2

Illus., colorplates, index
2-Book set, clothbound, **$80**

CONTENTS

Book A

Ontogeny of Hematopoietic Development and Stem Cells

Introduction (Till); Ontogeny of hematopoietic organs (Le Douarin); Yolk-sac stem cells (Weissman); Fetal hepatic hematopoiesis (Johnson); Stem cells in vitro (Dexter); Evaluation of stem-cell function (Till); Kinetic behavior of cell populations (Rubinow); Stem-cell heterogeneity (Phillips); Histamine H_2-receptor and CFU-S (Bryon); Stem cell and clonal origin of myeloproliferative disorders (Fialkow)

Erythrocyte Differentiation and Regulation

Introduction (Marks); Erythropoietic progenitor cell regulation (Axelrad); Competition for stem cells (Van Zant); In vitro differentiation studies (Gregory); Commitment to erythroid differentiation (Houseman); Erythroleukemia cell differentiation (Rifkind); Cell-cycle and induced erythroleukemia differentiation (Marks); Modulation of in vitro erythropoiesis (Adamson); Membrane changes during Friend-cell differentiation (Bernstein); Effect of DMSO and *n*-butyrate on Friend and HeLa cells (Neumann); Analysis of Friend-cell differentiation (Eisen); Regulation of globin genes (Nienhuis); Globin gene in Friend cells (Dube); Sequential gene expression in Friend cells (Obinata)

Granulocyte and Monocyte Differentiation and Regulation

Introduction (Moore); Regulation by colony-stimulating factors (Burgess); Inhibitors of hematopoiesis (Cline); Probes for hemopoietic progenitors (Price); Macrophage activation (Cohn); Leukemic myelopoiesis (Moore); Granulopoietic influences in acute myeloid leukemia (Greenberg); Normal differentiation in leukemia (Sachs)

Lymphocyte Differentiation and Regulation

Introduction (Cantor); Lymphoid ontogeny and TdT (Silverstone); Regulation of lymphocyte differentiation (Goldstein); HLA antigens (Strominger); Classification of human leukemia (Sallan); B-cell development and growth regulation (Melchers); Murine IgD and B-lymphocyte differentiation (Uhr); Differentiation of cytotoxic T lymphocytes (Sundharadas)

Book B

Viruses—Transformation and Differentiation

Introduction (Baltimore); Properties of the Ki-MSV and the Friend SFFV (Scolnick); Murine C-type virus diversity (Elder); Akv and MCF viruses (Rommelaere); Receptor-mediated leukemogenesis (McGrath); *Fv-2* resistance gene in mice (Steeves); FOCMA: A tumor-specific antigen (Hardy); Lineage-specific leukemic transformation (Graf); T-lymphocyte differentiation and transformation (Waksal); Virus infection of mouse hematopoietic cells (Teich); Suspension tissue culture and virus information (Gallo); Virus from human lymphoma cells (Kaplan)

Cytogenetics and Expression of Cell-Surface Antigens

Nonrandom chromosome abnormalities (Rowley); Genetic control of hemoglobin production (Skoultchi); Biosynthesis of T25 (Thy-1) (Hyman)

Marrow Architecture and Microenvironment

Hematopoietic stem-cell seeding of a matrix (Fliedner); Factors controlling stem-cell proliferation (Lord); Marrow-cell kinetic heterogeneity (Shackney)

Clinical-Pathological Relationships and Differentiation of Human Hematopoietic Tumors

Introduction (Lennert); Differentiation in B- and T-cell disorders (Catovsky); Membrane phenotypes in human leukemia (Greaves); Adult lymphoid neoplasias of T- and null-cell types (Koziner); Membrane markers in human lymphoid malignancies (Seligman); Immunoblastic lymphoma (Rappaport); Malignant lymphomas as models (Lennert); Biology of the human lymphomas (Epstein); Cytokinetic model for lymphomas (Lukes)

Summary (Clarkson)

Volume 1
Control of Proliferation in Animal Cells
Edited by **B. Clarkson R. Baserga**

"Here one finds in one mammoth volume a cross section through nearly all the new frontiers of this relatively young branch of biology." —General Embryological Information Service

"Overall, this book is useful both for the specialist to broaden his outlook and for the nonspecialist to become more familiar with an exciting field." —R. Shields, Cell

1974, 1029 pp., Illus., index Clothbound, **$60**

Volume 2
Proteases and Biological Control
Edited by **E. Reich D.B. Rifkin E. Shaw**

"... leads one to the conclusion that proteolysis may well play as widespread and important a role in regulation as allosterism and post-transcriptional modification of amino acid side chains." —G. Reeck, ASM News

"... a fascinating and informative book, a pleasure to read." —B. Kassell, Science

1975, 1022 pp., Illus., colorplates, index Clothbound **$60**

Volume 3
Cell Motility
Edited by **R.D. Goldman T.D. Pollard J.L. Rosenbaum**

"There have been numerous recent symposia on various aspects of cell motility, but nowhere will one find as broad an overview or as deep a factual treatment as in Cell Motility." —R.E. Stephens, BioScience

1976, 1404 pp., Illus., index 3-Book set, clothbound, **$90**

Volume 4
Origins of Human Cancer
Edited by **H.H. Hiatt J.D. Watson J.A. Winsten**

"A comprehensive and useful look at the many facets of contemporary cancer research." —David Baltimore, Massachusetts Institute of Technology

1977, 1889 pp., Illus., index 3-Book set, clothbound, **$75**

Circle No. 17 on Reader Enquiry Card.

mosquito breeding places in Sierra Leone, through Sir William Macregor's enlightened sanitation measures in Lagos, Malcolm Watson's brilliant successes in Malaya and then the controversial malaria control project of Indian Army's barracks at Mian Mir, near Lahore. (The discussion of the latter episode is particularly well researched and lucid).

A good popular account of the natural history of mosquitos precedes the description of the successful control of yellow fever and malaria in Panama, by General William Gorgas. This is also well told and provides many little known details of Gorgas's splendid effort in spite of the differences he had with Goethals, the commander of the Panama zone.

The next important phase of the fight against malaria opened in the early 1930s in Italy and the conflict between Angelo Celli's ideas imbued by his social reformer's spirit and Alberto Missiroli's growing faith in the new technology of control by elimination of adult Anopheles from human dwellings, is well brought out. The powerful stimulus of L. W. Hackett of the Rockefeller Foundation's research team in Italy is given a proper place in this part of the story.

Further chapters present the dramatic impact of malaria epidemics in Mauritius, Sri Lanka (Ceylon), Brasil and Egypt in the 1940s and the dawn of the technique of insecticidal spraying of houses as a promising method of control. The apparent failure of the Sardinian project of "species eradication", carried out between 1946 and 1951, was a prelude to the emerging concept of malaria eradication programmes which were set up at that time in Greece, Venezuela and elsewhere.

The last two chapters, entitled "India the model for the world" and "Relapse", cover the past 20 years of the global malaria eradication programme launched, coordinated and supported by the World Health Organisation since 1957. Here the author attempts to deal in a simplistic manner with all the complex problems that bedevilled this great and overambitious international endeavour. This part of the book fails to appreciate the many positive achievements of malaria eradication and seems to concentrate on pointing out the various deficiencies and errors—some true, others imaginary. However true certain remarks may be, the author's tendentious debunking of this major effort, with the air of someone who knows all the answers, is grossly unfair. His critical comments on the recent realistic appraisal by the WHO of the need to assess the costs of malaria control in relation to the means of the tropical countries concerned, reveal his scant acquaintance with the socio-economic aspects of health problems of developing countries.

Oddly enough, there is no mention of the fact that the most stringent criticisms of the strategy of the global programme of malaria eradication came from the remarkable, self-auditing study of the World Health Organisation, namely the well known Annex 13 of the Director's General Report to the Twenty-Second World Health Assembly in 1969.

The achievements of the past 50 years of chemotherapy of malaria as an important weapon for prevention and treatment of this disease are omitted from this otherwise comprehensive study.

In summary, this is a patiently researched and very readable story of events that formed the milestones of the relatively recent knowledge of the transmission of the agent of malaria and its control by the attack on the vector. It is regrettable that the appraisal of all aspects of the attempted global malaria eradication is somewhat unbalanced, by concentrating on its failures.

There are several minor errors in the names of persons or titles of books (for example, Beauperthuy not Beauperthy; Daniels and not Daniel; Macdonald not Mac Donald; Ross's romance was *The Spirit of the Storm* not *The Spirit in the Storm*). Some footnotes are perplexing: thus, the one on p40 says: "Ross knew that it was the female that sucked blood but military man, that he was, he persisted in calling her 'he' ". A few instances of purple prose such as Ross's "adrenaline pump" or his "ecstasy of Ego" are jarring in the generally clear and pleasing style of a book that should nevertheless interest a wide circle of readers. The illustrations are well chosen: the copious notes are generally relevant and the list of references is valuable even though it shows some inexplicable lacunae.

The blurb on the cover mentions that "The extraordinary story of the crusade against malaria is told here for the first time". This is simply not so, because several excellent books on the subject were published during the not too distant past: Paul Russell's *Man's Mastery of Malaria*, of 1955, is still one of the best of them. Moreover the recent ups and downs of malaria eradication have been dealt with fully in published reports of the WHO and in numerous other articles. ☐

L. J. Bruce-Chwatt is Professor Emeritus of Tropical Hygiene in the University of London, a former staff member of the WHO, and a member of the WHO Expert Panel on Malaria.

New books from
Blackwell

Behavioural Ecology: an Evolutionary Approach
Edited by J.R. Krebs and N.B. Davies. 1978. 512 pages, 140 illustrations. Cloth £18.00, paper £8.50
Research workers, currently active in the field of behavioural ecology, present an up-to-date account of theoretical ideas and show how these have been tested by observation and experiment. Topics covered include feeding behaviour, social organisation, sex and mate choice, life history strategies, communication and decision making. The simple and clear presentation should make this an ideal undergraduate course text.

Spermatozoa, Antibodies and Infertility
Edited by Jack Cohen and W.F. Hendry. 1978. 224 pages, 35 illustrations. £11.00

Fungal Genetics
Botanical Monographs Volume 4, by J.R.S. Fincham, P.R. Day and A. Radford. Fourth Edition, November 1978. 448 pages, 113 illustrations. About £20.00

Diversity of Insect Faunas
Ninth Symposium of the Royal Entomological Society, edited by L.A. Mound and Nadia Waloff. November 1978. 224 pages, 68 illustrations. About £12.50

Sedimentary Environments and Facies
Edited by H.G. Reading. 1978. 336 pages, 280 illustrations. Cloth £22.50, paper £13.00

The Economy of Nature: a Textbook in Basic Ecology
Robert E. Ricklefs. 1978. 464 pages, 242 illustrations. £6.75

Ecological Processes in Coastal Environments
Nineteenth Symposium of the British Ecological Society and First European Ecological Symposium, edited by R.L. Jefferies and A.J. Davy. Early 1979. 512 pages, 120 illustrations. About £20.00

Introduction to Modern Mycology
Basic Microbiology Volume 7, by J.W. Deacon. December 1978. 128 pages, 80 illustrations. Paper, about £3.00

Lecture Notes on Invertebrate Zoology
M.S. Laverack and J. Dando. Second Edition, December 1978. 288 pages, 260 illustrations. Paper, £5.50

Microbial Ecology: a Conceptual Approach
Edited by J.M. Lynch and N.J. Poole. Early 1979. 288 pages, 120 illustrations. Cloth about £18.00, paper about £9.50

Ecological sanity

Kenneth Mellanby

Reconciling Man with the Environment. By Eric Ashby. Pp.104 (Oxford University Press: Oxford and London; Stanford University Press: Stanford, California, 1978.) £4.25; $7.95

LORD ASHBY is a distinguished botanical research worker. He was Professor of Botany in Sydney and in Manchester. He was active in establishing the Society for Experimental Biology in the 1930s. He was also the first chairman of the Royal Commission on Environmental Pollution, set up by the British government in 1970 to "advise on matters, both national and international, concerning pollution of the environment; on the adequacy of research in this field; and the future possibilities of danger to the environment." The experience gained in this career has given him an ability to survey the environmental scene with unusual perspicacity.

In this book Lord Ashby is particularly concerned with the ways in which public opinion may stimulate governments to cope with hazards to the environment. He describes this as a "chain reaction", in which the interest of the public is first ignited by the media, then the hazards are assessed by scientists and economists, and, finally, political action is taken. This action is often based on a compromise between opposing interests, and may take into account both objective data and subjective values. In general the British pragmatic approach, with attention to concrete effects on man's surroundings rather than on rigid standards setting levels of emission, is shown to be most effective.

Successes and failures to protect the environment are illustrated by several examples. Lord Ashby describes graphically the struggle over Upper Teesdale in the north of England, where an area of unique botanical importance was the most convenient—and least expensive—site for a reservoir, needed for the industrial development of an area of potentially high unemployment. Although the reservoir was eventually built, the botanists and other conservationists who opposed its construction were given a good hearing and substantial modifications were made in the scheme to try to reduce its ecological impact. Funds for research in the area were also provided by the commercial interests most involved. Lord Ashby infers that this demonstrates how, by the 1960s in Britain, public opinion had been educated. It is suggested that at an earlier date industrial necessity would have been encouraged to ride roughshod over the site, destroying the Teesdale Sandwort and the Spring Gentian.

Of more general topics, the examples of the great improvement of the quality of the air in British cities, and the moderate improvement of the state of the water in British rivers, both in the past quarter of a century, are quoted. These improvements have cost both industry and the public a considerable amount of money, something which might have not been tolerated fifty or a hundred years ago. In the nineteenth century many attempts to persuade Parliament to legislate were unsuccessful before the passing of the first Alkali Act (controlling little else but acid emission to the air) in 1867. The more drastic Clean Air Act of 1956 was generally welcomed, even if some of its most stringent provisions have not yet been adopted in many parts of the country.

In recent years there has been serious controversy about waste disposal, particularly of poisonous substances. Lord Ashby's Royal Commission realised this was a danger, and so reported strongly but soberly in its 1971 report. The government did nothing—the programme for parliamentary legislation was full up. The matter was then taken up, more shrilly, by various voluntary bodies of citizens concerned with the environment. They made the case more emotionally, but still relied for the main on a reasonable assessment of the dangers. Nothing happened—Parliament was still too busy. Then a large number of drums of cyanide were were found, with their labels inefficiently removed, in an area of wasteland used as a childrens' playground. It was alleged that this "flytipping" occurred with the tacit encouragement of the driver's employing company. There was an immediate outcry, and within days Parliament passed a bill to prevent a recurrence.

However, I think that Lord Ashby may be overstating the contribution to the protection of the environment by the media, and of any widespread change in "public opnion". In the case of the toxic wastes, the drum of cyanide were a real and easily demonstrable danger, which dramatically highlighted the Royal Commission's warnings. Often it seems that there is only a public outcry about environmental problems after they have been solved by backroom experts using unglamorous means. This may be illustrated by changes in air pollution. It is generally believed that the improvement in Britain occurred because of action following public outcry, when it was reported that the great London "smog" of 1952 killed off, prematurely, some 4,000 elderly, ailing and bronchitic citizens. The resulting Clean Air Act is thought to have been the main instrument of change. In fact London's air even by 1952 was far cleaner (or, perhaps, less filthy) than it had been in the nineteenth century, in the days of Dickens. The improvement was mainly because it became cheaper and easier for industry to use clean fuels like oil, gas and electricity, and because the competent and well informed Alkali Inspectorate was beavering away controlling industrial emissions years before the Act was passed in 1956. At the same time many householders had already stopped burning raw coal before regulations compelled them to do so. Legislation was useful, but only in accelerating a change already taking place.

The situation regarding pesticides is also interesting. Lord Ashby says that had not Rachel Carson published *Silent Spring* in 1962 "public apathy about the hazards of pesticides might have persisted a decade longer". This is quite true, but is hardly relevant to the way in which pesticides were controlled, at least in Britain. Here naturalists and ornithologists in particular had been concerned with the deaths of thousands of seed-eating birds each spring from about 1955 onwards. The situation had been investigated by them and by scientists in government laboratories, and seed dressings of aldrin and dieldrin on spring-sown wheat implicated. Some time before *Silent Spring* was published the voluntary ban on these seed dressings on spring wheat was operated, with the result that the bird deaths were greatly reduced. Even before that the successful Pesticides Safety Precautions Scheme was set up with the result that no new chemical causing comparable ecological effects on non-pest species has been introduced. It is possible to argue that the wide public reaction to pesticides, sparked off by Rachel Carson, has generally been counter-productive. Before the book appeared, informed public opinion had taken effective action. After the book aroused uninformed opinion, many, particularly in developing countries, have been denied the use of safe pesticides and so the incidence of, and death toll from, diseases like malaria has greatly increased.

However, I only disagree with Lord Ashby in the way we define "public opinion". Effective environmental control has required the support of the informed public, but not of the masses

Reidel's Autumn List

Nonlinear Equations in Physics and Mathematics

A. O. BARUT (ed.)

The main topics of the book are: classical solvable nonlinear evolution equations; integrable dynamical systems; inverse scattering method; nonlinear equations in lattices and in continuum physics; solitons and occurrence in physics; and applications to quantum field theory and elementary particles.

483 pp, Cloth Dfl. 80,– / US $ 39.00
ISBN 90-277-0936-X

Atlas of Photomicrographs of the Surface Structures of Lunar Regolith Particles

A. CIMBÁLNIKOVÁ, O. RODE *et al* (eds.)

Contains 164 photomicrographs of examples collected by Russian automatic probes from the lunar mare and highland region.

about 250 pp. Cloth Dfl. 80,– / US $ 39.00
ISBN 90-277-0877-0
Not for sale in the Socialist Countries

High Pressure Chemistry

HARTWIG KELM (ed.)

607 pp. Cloth Dfl. 125,– / US $ 59.00
ISBN 90-277-0935-1

Surveillance of Environmental Pollution and Resources by Electromagnetic Waves

TERJE LUND (ed.)

The book discusses a wide range of instrumental techniques and analytical methods, designed to provide information about a vast number of environmental parameters.

422 pp. Cloth Dfl. 80,– / US $ 39.00
ISBN 90-277-0949-1

Excited States in Quantum Chemistry

CLEANTHES NICOLAIDES &
DONALD BECK (eds.)

A thorough review is presented of theoretical methods and results on electronic excited states from the beginning. This is accompanied by experimental and phenomenological articles on Photoelectron Spectroscopy, Lifetime Measurements, and the role of the Excited State in Organic Photochemistry.

565 pp. Cloth Dfl. 115,– / US $ 59.00
ISBN 90-277-0961-0

Infrared Astronomy

GIANCARLO SETTI (ed.)

Topics range from problems of interstellar matter and dust and star formation, to the problems of extragalactic infrared sources.

352 pp. Cloth Dfl. 80,– / US $ 39.00
ISBN 90-277-0871-1

Spacecraft Attitude Determination and Control

JAMES WERTZ (ed.)

It is the first comprehensive presentation of data, theory, and practice in attitude analysis. Because of the extensive cross-references, complete index, and 13 technical appendixes, the book can either be a self-teaching text or a reference handbook.

876 pp. Cloth Dfl. 90,– / US $ 44.00
ISBN 90-277-0959-9

Electrons and Phonons in Layered Crystal Structures

TERENCE WIETING &
MICHAEL SCHLÜTER (eds.)

It provides comprehensive treatments of the physics of pure inorganic materials and includes elemental, binary, and mixed crystal systems.

about 500 pp. Cloth Dfl. 150,– / US $ 73.00
ISBN 90-277-0897-5

Dismantling the Memory Machine
A Philosophical Investigation of Machine Theories of Memory

HOWARD BURSEN

The author criticises the trace theory and shows that there can be no scientific explanation of human memory.

166 pp. Cloth Dfl. 40,– / US $ 19.50
ISBN 90-277-0933-5

On the Normal and the Pathological

GEORGES CANGUILHEM

The book tries to integrate some of the methods and attainments of medicine into philosophical speculation.

about 220 pp. Cloth Dfl. 60,– / US $ 29.00
ISBN 90-277-0907-6 Paper Dfl. 30,– / US $ 14.50 ISBN 90-277-0908-4

Nuclear Magnetic Resonance Spectroscopy in Molecular Biology

BERNARD PULLMAN (ed.)

The volume contains a thorough examination of the present status and future possibilities of the developing field of the utilization of nuclear magnetic spectroscopy in molecular biology.

546 pp. Cloth Dfl. 115,– / US $ 56.00
ISBN 90-277-0932-7

Sociobiology: Sense or Nonsense?

MICHAEL RUSE

'It is the best written to date about the whole scope of sociobiology, including a consideration of its basic biological principles, the philosophical basis of its varied extensions, and the conflicts that have grown up around its human applications'.
EDWARD WILSON.

about 250 pp. Cloth Dfl. 60,– / US $ 29.00
ISBN 90-277-0940-8 Paper Dfl. 20,– / US $ 9.95 ISBN 90-277-0943-2

Ionospheric Techniques and Phenomena

ALAIN GIRAUD & MICHEL PETIT

Equal emphasis is placed on the techniques of ionospheric measurements, and on the interpretation of ionospheric phenomena considered as tracers of atmospheric and magnetospheric processes.

284 pp. Cloth Dfl. 85,– / US $ 38.00
ISBN 90-277-0499-6

Microphysics of Clouds and Precipitation

HANS PRUPPACHER & JAMES KLETT

Emphasis is placed on presenting a comprehensive description of the various mechanisms of cloud microphysics which lead to the formation of cloud and precipitation particles, both individually and in populations.

728 pp. Cloth Dfl. 85,– / US $ 39.00
ISBN 90-277-0515-1

Scientific Information Transfer: The Editor's Role

MIRIAM BALABAN (ed.)

The book can be used as a reference work. It discusses attitudes, policies, prejudices and problems of editors, publishers and scientists. The diverse aspects of editing towards advancing scientific information transfer are also analysed.

718 pp. Cloth Dfl. 70,– / US $ 34.50
ISBN 90-277-0917-3

The Book of Ingenious Devices

Kitāb al-Ḥiyal

by the Banū (sons of) Mūsà bin Shākir
Translated and annotated by DONALD HILL

Written in Baghdad about 850 A.D., the book contains the original illustrations of more than a hundred devices, of which most are trick vessels.

about 278 pp. Cloth Dfl. 130,– / US $ 63.00
ISBN 90-277-0833-9

Technics and Praxis
A Philosophy of Technology

DON IHDE

Technology as a specific theme for philosophic inquiry is relatively recent. This book explores themes in what is becoming known as the philosophy of technology which relates technology to the central concerns of epistemology and ontology.

about 192 pp. Cloth Dfl. 45,– / US $ 21.95
ISBN 90-277-0953-X Paper Dfl. 22.50 / US $ 8.50 ISBN 90-277-0954-8

The Beginnings of Greek Mathematics

ÁRPÁD SZABÓ

Linear incommensurability, Euclid's theories, and Elea's philosophy, are all discussed.

about 360 pp. Cloth Dfl. 100,– / US $ 47.50

Butterworths announce new titles in three major series

Conservation in the Arts, Archaeology and Architecture

The Museum Environment

GARRY THOMSON

Written for museum curators and workers in conservation research, the author describes the principles and techniques of controlling the environment in order to minimise the damaging effects of light, humidity and air pollution on museum exhibits.

Designed both for instruction and reference, it will be an indispensable companion volume to the subsequent titles in the series which deal with the conservation of specific objects and materials.

'This book should be required reading for all who have works of art in their keeping.'
Sir Norman Reid, Director, The Tate Gallery, London.

246 x 189 mm *284 pages* *Illustrated* *0 408 70792 5* *£16.00* *US $32.00*

Butterworths Monographs in Chemistry

Solvent Extraction in Flame Spectroscopic Analysis

M. S. CRESSER

Presents details of tried and tested methods of solvent extraction as applied to flame spectrometry and methods used in other branches of chemistry which can be applied with little or no modification. Specialist readers are referred to the original publications by a very extensive bibliography, and detailed introductory material is included for those unfamiliar with the field. Application of the technique to individual elements is discussed for most of the metals. This book will undoubtedly save many hours of literature searching by those chemists wishing to solve their particular problems by means of flame spectrometry.

234 x 156 mm *210 pages* *Illustrated* *0 408 71307 0* *£15.00* *US $30.00*

Studies in the Agricultural and Food Sciences

Plant Breeding for Pest and Disease Resistance

G. E. RUSSELL

Provides a comprehensive review of work on breeding for resistance to all the major groups of pests and diseases of important agricultural and horticultural crops throughout the world. The pests and causal pathogens include fungi, bacteria, viruses, insects, nematodes, vertebrate pests and parasitic weeds. Professor Russell describes and contrasts the kinds of resistance that are available for plant breeders to exploit, explains the principles on which breeding programmes are based, and describes the methods used.

The book contains more than 1500 references to original research papers. Plant breeders, plant pathologists, entomologists and agronomists will find it particularly valuable, as will postgraduates in applied biology.

in general. I realise that this view will today be castigated as 'elitist' but it is nevertheless true. Where mass opinion has been inflamed, overreaction has often occurred, unsubstantiated statements have been put forward, and eventually there has been a 'backlash'. This is being experienced in many Western countries today, where the majority of the population are becoming bored with the environment. The uninformed and over-reacting 'environmentalists', preaching doom and gloom, are becoming increasingly discredited.

Lord Ashby is certainly too well informed to have any truck with the doom and gloom brigade. He considers that man has been, to some extent, reconciled to his environment, and that this is a "qualified success story". He does not conceal the fact that real damage occurs, and he indicates how this damage may be mitigated But he concludes his book by pointing out other, real reasons for concern. These are man's prodigal use of non-renewable resources and the difficulty those people with different ideologies have of living together in harmony. The final, and greatest danger, is thus political. The only hope is that mankind will learn from the qualified success in the environmental field. Here the cumulative effects of wise decisions (what Lord Ashby calls "wise medium-term microdecisions, each clarifying the shape of the decision that needs to follow") has produced a promising result. We can only hope that the problems of diminishing resources and political incompatibility will be solved in the same unspectacular way, by the efforts of the responsible minority, not be a tumult promoted by the media. □

Kenneth Mellanby is editor of the International Journal Environmental Pollution.

Politics of atomic energy

L. Rotherham

Nuclear Power and the Energy Crisis: Politics of the Atomic Industry. By Duncan Burn. Pp. 352 (Macmillan: London, 1978.). £12.

In his preface, Duncan Burn suggests that reviewers will be able to point out that some things are left out from this book but that the omissions will not affect the argument presented. There is a selected bibliography which includes about 100 items, and references in the text must number 700–800 Although the same reference may appear several times, no one would wish to say that the author has not carried out his work thoroughly. Some references unfortunately are useless: for example, taking only chapter 10, we find ref. 188/40—"I am following in this notes of discussions I had . . . " or 188/53—"This view was expressed to me early in 1964 by a member of the CEGB"—why not say which member, so that it can be authenticated?; or 191/109—"I had discussions at the time".

One would not wish to question the authenticity of the author's statements but he might have heard what he wanted to hear and we cannot say. Where he refers to published work, his excerpts seem to be exactly correct but his comments and his selection seem to be aimed to sustain his own opinions, and in the light of history that hardly seems necessary.

If this justification is the first theme of the book, a second is that the assessment of tenders for the Dungeness B power station was mishandled by the Central Electricity Generating Board (CEGB) and the Atomic Energy Authority (AEA), mainly due to the overwhelming influence of the AEA; and finally, it is suggested that the Government shares in the blame by interference in technical decisions where it lacks competence. These three themes are linked, of course.

The tenders for Dungeness B were received in 1965 and at the time virtually all British experience was in gas-cooled nuclear reactors, whereas in the United States nearly all experience was in water cooled reactors (LWRs) and in both cases the early experience was taken from military applications. In Britain, Calder Hall (a gas-cooled station) had been operating well since 1957 and rather larger stations had been commissioned for the CEGB in 1962 and 1963 These stations are still operating. Capital costs of the CEGB stations were higher than had been assumed but, of course, they are never lower and a subsequent de-rating of some of the stations amounted effectively to a further increase in capital costs. These facts are quoted in the book although they were not all known in 1965. Good influences such as the improvement in fuel element life are not quoted. It will be interesting at a later date to make a retrospective study of the cost of generating from these nuclear stations to compare with life-time figures from LWRs and with fossil fired stations. It is too early to say that the full truth has been revealed and that all is disaster.

In America, progress was through a series of subsidised demonstration reactors but this changed dramatically in 1963 when the Oyster Creek LWR power station was ordered. The quoted price was so low that it was regarded as being either heavily subsidised or a lost leader intended to sweep the market. Chapter 4 deals with the quick increase in costs between 1963 and 1966 but Oyster Creek did establish the LWR as probably the lowest cost system and it was accepted throughout the world, except in Britain, Canada and Russia.

In 1965, the advanced gas-cooled nuclear reactor (AGR) was expected to have higher initial costs than the LWR but lower operating costs as it was designed to produce steam at higher temperatures and pressures than the LWR and was matched to the large turbogenerators then being standardised on the CEGB system. Experience of the AGR was confined to the small demonstration reactor at Windscale, and the difficulties of extrapolation to larger sizes, later experienced also in the Magnox reactors, were not appreciated.

The reader of the book might infer that, in 1965, US experience was uniformly good, which it was not then nor always subsequently, whereas British experience was uniformly bad, which also was not true. It was in a different atmosphere from the one described by Duncan Burn that the Dungeness B assessment was made.

The CEGB procedures for tender assessments were well known within the Board and understood by those plant manufacturers who submitted tenders. It was the responsibility of specialist engineers, within the Board, to clarify any points of uncertainty in direct and confidential discussions with the plant manufacturers and, on the basis of their own calculations, to report at length on which submission best met the Board's needs In the case of nuclear power stations the procedure had become more complicated by the concept of 'turnkey' contracts which had been introduced and, in the particular case of Dungeness B and contrary to the view expressed in the book, by the exceptional amount of detailed design data provided It would have been impossible to proceed without very great help from the AEA, but the responsibility for a decision rested with the Board.

In chapter 10, it is stated explicitly that the assessment was biased and much of the blame is attached to the AEA, which is also accused of exerting excessive pressure on the CEGB. For example, on p163 it is said "in going AGR, the CEGB did so under the strongest pressure from the AEA" I cannot recall any meeting between the executive members of the CEGB and the members of the AEA at which pressure was even suggested and, if within the assessment team itself, anything was done which was unreasonable, I would have expected it to be resisted strenuously None was reported to the Board.

The conclusion was wrong for a very different reason. The extent of the extrapolation from the Windscale AGR to full scale was miscalculated and at Dungeness B, it was followed by some very bad engineering Part of the explanation for the miscalculation must be attributed to the fact that the CEGB had inadequate strength in nuclear matters to arrive at a conclusion contrary to that of the AEA or even to differ appreciably from their opinions. This was a matter for concern in 1965 and it still is.

The usual purchasing arrangement between a public utility and a manufacturer of plants outside the nuclear fields is dependent on a dialogue between two approximately equal sides This in the United States is roughly true for nuclear stations—also with little intervention from the national laboratories. In Britain, only fossil-fired power stations are treated in this way and the CEGB has an adequate engineering and R&D effort for a balanced discussion to take place, but in the nuclear field there is a single design and construction company—National Nuclear Corporation (NNC)—heavily criticised in the book) which is dependent on the AEA, as is the nuclear fuel company BNFL and, in addition, the main R&D resources lie with the AEA. It is very difficult to say where responsibility lies and the CEGB is not strong enough to deal adequately with the technical problems of new systems, in direct discussions with the manufacturers.

It is this centralisation of technical ability in the AEA which Duncan Burn also sees as contributing to the inability of Government sensibly to take technical decisions, and this is discussed at length in the final chapter of the book. He would wish to see a competitive arrangement, based on American experience, with the AEA and the Government largely withdrawn from the discussions between the generating boards and the manufacturers However, competition in the United States has reduced to only two firms to supply a large market Probably only one could survive here, although not necessarily the present NNC. The Government cannot withdraw entirely, for, as the main source of finance for the building of power stations and for the development of nuclear stations, it is entitled to ask the questions which any prudent banker would ask. And, especially in safety matters but elsewhere, too, there are political issues to consider.

The AEA position, as virtually the sole repository of information, will be changed with the recent decision to abandon the steam-generating heavy water reactor in favour of LWR and the main relationship might become direct between the generating boards and the overseas suppliers of LWR stations. But will it change very much if the board's negotiations have to be with the NNC and if the NNC is not free from the AEA? Even if the change is made, then, will it persist for the next Fast Breeder Reactor (FBR) the authorisation for which is long overdue, if it is to be available at the end of the century? Ought the CEGB to be happy with a situation in which its own R&D effort is concentrated largely on the operational problems of its already purchased reactors when it is the generating boards who will need the FBR by the end of the century?

There are many other questions raised by Duncan Burn's analysis and one can only hope that the book will stimulate more urgent consideration of the answers needed. It is worth reading for this alone but there is much more that the reader will find interesting and provocative. The only serious criticism would be that the views expressed would have carried greater weight if they had been presented with greater balance and fairness Even this is perhaps excusable, as it is a short book in which to cover everything on a big subject. □

L. Rotherham was Assistant Controller and Director of Research at the UK Atomic Energy Authority's Industrial Group from 1950–58, and a Board Member of the UK Central Electricity Generating Board from 1958–69.

Futurologists examined

Eric Ashby

World Futures: The Great Debate. Edited by Christopher Freeman and Marie Jahoda. Pp. 416. (Martin Robertson: Oxford, 1978.) £15.

In 1973 the Science Policy Research Unit (SPRU) at the University of Sussex brought a refreshing voice of sanity into the overwrought and querulous debate about limits to growth. In a collection of essays called *Thinking About the Future,* H. S. D. Cole and his colleagues courteously and convincingly exposed the irresponsible prognostications of doom put out under the auspices of the Club of Rome. If SPRU had made no other contribution to contemporary thinking, this work alone would have justified their existence. The team has now produced a second book which, in my view, is even more important. It sets out to make a sober analysis of the views of 16 "major authors" who have published forecasts about the possible futures or fates awaiting the world as it moves into a phase of too many people, too little food, too dangerous energy, too attenuated mineral resources: Kahn, with his cocky optimism that all will come right (if you don't mind a few wars and some pretty extensive starvation) provided we stay on the path of *laissez faire* capitalism; Forrester, rattling the bones of a computer in the face of society; Schumacher, wistfully hoping that trans-national corporations will metamorphose into cosy little cottage industries; Heilbroner, who sees hope only in authoritarian government; Tinbergen, who believes that a genuine crisis will mobilise loyalty among people for the common good; Kosolapov, whose Marxist optimism brings him astonishingly close to the capitalist optimism of Kahn; and 10 others: Spengler, Ehrlich, Meadows, Dumont, Mesarovic, Leontief, Kaya, Herrara, Modrzhinskaya and Galtung.

Christopher Freeman and Marie Jahoda have organised their material in a bold and successful way. They propose that the beliefs of the 16 authors whose work they consider, and the beliefs of their own team (by no means unanimous) can be roughly—and they emphasis that it is roughly—classified into three categories· conservative, reformist and radical; each with a distinctive "world view" which sets boundaries to the assumptions each author makes about possible futures. Thus, the radical may regard revolution as a necessary prelude to a future equilibrium; the reformist would favour big, but incremental, changes; and the conservative would question whether the background needs to be changed at all. They then make an equally bold generalisation about possible futures. Wisely they eschew computer scenarios which, as they say (p70), "disguise rather than reveal the extent to which their results are dependent on their assumptions and data". Instead they propose four options high growth accompanied by a persistence of the present inequalities between richer and poorer nations; low growth, also accompanied by the present inequalities; high growth accompanied by a major and persistent narrowing of the gap between rich and poor; and low growth, also accompanied by a narrowing of the gap between rich and poor. They then examine, in impressive detail, the possible consequence of these four options as they are perceived by conservatives, reformists and radicals. It is a skillful discussion of the interaction of three different political attitudes on four different possible futures for society. It is a simple framework on which facts and ideas can be attached, quite the most useful one which has yet been designed. In her eloquent conclusion to the book, Marie Jahoda sets out its three aims: to make a contribution to forecasting methodology, to take a substantive position in the world futures debate, and to offer some ideas for considering deliberate actions and choices in the less distant future which may affect the fate of the next two or three generations. They are modest aims, and all three of them are achieved.

No one is competent to take part in this 'great debate' who has not mastered the relevant facts about forecasts for population, food energy and mineral resources. These facts are set out in four introductory chapters, which cover familiar ground, although some of the conclusions drawn from the facts will be challenged. No one will dispute the recklessness of making predictions about population: the estimates by the 16 futurologists differ by almost an order of magnitude! Over food supplies the authors conclude that the limiting factor is not the amount of food which can be produced; it is the lack of means to distribute the food equitably and the lack of money in the Third World to pay for food. This view will be disputed by some experts, although no one is likely to underestimate the disgraceful mismatch between butter mountains in one part of the world and starvation in another. Over mineral resources the authors are equally optimistic: there will be shortages of specific materials but—in their view—these shortages will not be likely to have a desperate impact on the quality of life.

The Achilles heel for a stable future, the authors say, is energy If there is not a sufficient supply, all else—food, industry and peace—is put at risk. If a sufficient supply is ensured by massive development of fast breeder reactors and the like, then other dangers which have had plenty of publicity—what to do with wastes, what to do with terrorists—take the place of the dangers due to insufficient energy. The authors favour a eclectic solution, with much more attention than there is at present being paid to energy from the sun, wind and tides. Again, some experts will challenge this view as unrealistic

Differences of opinion over the content of these chapters do not, however, affect the main argument of the book, which is that the first symptom of crisis over food, energy, or resources will not be physical shortages of these things: it will be social and political disturbances; and it is to these that emphasis should be given, and given now.

The important and original part of the book carries a set of sober speculations. The authors make a list of seventeen features which play a part in determining the quality of life of ordinary citizens The list includes intangibles, such as geopolitical issues, and tangibles, such as food, health, transport and energy; and they add to these features the two emotive words which have drawn men into war and revolution for millennia: liberty and equality. How would conservative, reformist and radical regimes act toward these emotive words and the seventeen parameters for the quality of life in conditions of high or low economic growth, and at greater or lesser levels of equality? Into this matrix of three world views × four conditions of growth and equality × seventeen features contributing to quality of life (204 in all) the authors pack their conjectures for possible futures The matrix covers thirty-four pages; it contains, in my view, more practical common sense (which is the attribute which matters most in the Civil Service or in Government), and more credible assumptions (which are the most important ingredients for sound economic advice) than I have read in any other document about forecasting. Of course, it makes sombre reading. High economic growth continued indefinitely leads to the absurdity of all unconstrained exponentials. Low economic growth continued indefinitely leads to frustrated expectations, and these in turn lead to conflict. Perpetuation of the present inequalities between rich and poor nations are a recipe for revolution and war. Reduction of present inequalities — even with some growth — makes demands for sacrifices from affluent nations which, so far, have met with a derisory response. (The world's annual expenditure on armaments is some 15 times more than the aid from affluent to third world countries.) Struggle, turmoil, revolution, stagnation: these are words which appear unpleasantly often in the matrix

But the SPRU team, despite ideological differences among them, do come to a firm conclusion Of the four options they propose, the one which offers the least dangerous prospect for mankind is the scenario for high growth and more equality: The conservative would hope to attain this by creating a larger cake of wealth so that poor nations could share it: the reformist would expect affluent countries to react only under threat to world stability, and then, no doubt dragging their feet, to make sacrifices so that poorer countries could 'leapfrog' into appropriate levels of industrialisation. The radical would rely on the seizure of political power by the workers, followed by a gesture of altruism (not apparent among workers at present) toward their poorer brothers in the third world.

The outstanding practical conclusion from the analysis is that the absolutely top priority, the need which should take precedence over all other needs, is to narrow the gap between rich and poor, both within and between nations. This is not an original sentiment; but the authors of this book do not just offer it as a pious hope. They press the point: that the way to reduce inequality is to devote massive resources to problems to which the affluent nations are paying very little attention: research and development (for instance) on tropical agriculture and on intermediate technology. They stress, too, that innovation is needed far more urgently in political institutions than in technology Anyone who reflects on the problems which lie ahead is brought up against the ugly prospect that the problems may not be soluble under a pluralistic democratic government. The alternatives are one or other version of authoritarianism. Is it practicable to devise an authoritarian pattern of government which requires obedience over principles (such as is already demanded by the Highway Code in the UK) but leaves individuals freedom (as motorists in the UK indeed have) to exercise their liberty (for example, when driving, provided they comply with the code)?

The high level of generalisation in this book constitutes its strength. Indeed, the authors themselves repeatedly remind the reader of the futility of specific technology assessment. Discontinuities make nonsense of such assessments. For instance, the National Resources Committee of the Department of the Interior in the USA made a thorough prediction of technological trends in 1937. They failed to forecast atomic energy, computers, radar, antibiotics, and World War II and its social consequences: no-one can blame them for these omissions, but this example, and scores of others like it, should make anyone sceptical about similar specific forecasts being made today. The paramount potential discontinuity, of course, is the finite possibility of a nuclear war. In a heroic chapter, the authors of this book tackle this problem too And it leads them to a sombre conclusion namely that a policy of disarmament among the great powers (which would entail a cessation of activities costing over $\$200 \times 10^9$

per annum) would itself precipitate a major social and economic upheaval.

In a world deluged with books, many busy people have to content themselves with reading the reviews and not the books themselves. It would be a great mistake to read only the reviews of this book. It is essential reading for anyone who wishes to participate in the debate about man's future with (as the authors put it) "informed imagination". □

Détente and dissent

Robert Lewis

Soviet Science. By Z. A. Medvedev. Pp. 262 (Norton: New York; 1978.) $10.95.

ACCORDING to the 'blurb' on its cover, Zhores Medvedev's latest book is

> "a brief history of science in the Soviet Union with an emphasis on the interaction between scientific and technological developments and the political goals of the Soviet government".

However, the potential purchaser should not be misled by this statement, for as the author himself admits in his introduction, this is not a book for those who wish to have a short and reasonably comprehensive account of the development of science and science policy in the Soviet Union since 1917. Indeed the years between 1917 and 1953 are summarily dealt with in five short chapters and a little over fifty pages. Furthermore these chapters contain several errors. For example, the author states that in the years 1922–28 science was directed at the government level by the People's Commissariat of Education, when, in fact, this commissariat was only one among a number of government organs involved in science policy-making and was becoming less important in this field. These initial chapters are padding which make the manuscript of better length for a book and which the publishers presumably hope will increase its marketability.

The real heart of Medvedev's book is an essay on science in the USSR under Khrushchev and Brezhnev with particular emphasis on the two themes of *détente* and dissent. The author restates his view that *détente* has not been a consequence of Soviet military weakness and is not a necessary condition for the continuing development of Soviet military technology. On the other hand he considers that it has had important consequences for Soviet scientists working in non-secret fields, bringing an acceleration in the renewal of links between Soviet and world science which had begun under Khrushchev. More Soviet scientists have travelled abroad and more articles have been published in foreign journals; the maintenance of informal contacts has become easier. This increased contact has strengthened the feeling among Soviet scientists that they, like scientists elsewhere, are participants in a universal scientific culture which is independent of any particular set of national values. This degree of cultural autonomy, reinforced by the high prestige which scientists have in Soviet society, has put them in a special position. Indeed, the author reports a conversation which he had with Kapitsa in 1967 when the latter suggested that the function of the United States' Supreme Court and the British House of Lords as independent arbiters in constitutional problems seemed to be falling morally on the Academy of Sciences of the USSR. These special conditions surrounding Soviet science are seen as major factors in the relatively high frequency of political dissent amongst scientists. Medvedev reviews the policies adopted by the Soviet government and the Communist Party to counter dissent by such means as the exercising of closer control over the award of higher degrees and promotion with the aim of preventing dissidents rising higher in the scientific hierarchy; he is, however, sceptical of the effectiveness of such measures.

Thus, the Soviet government, as the author points out, is in a dilemma. On the one hand the future progress and prestige of Soviet science, to which the government attaches great value, depends on international contacts—a simple instance is that, as a result of lengthy publication lags in Soviet journals and of the inability of most other scientists to read Russian, publication abroad is likely to be needed in the vital matter in modern science of establishing priority. On the other hand the closer attachment of Soviet scientists to the international scientific community and its norms and values increases their degree of cultural autonomy and consequently the problems of political control. The author does not offer any firm prediction of the likely outcome of this clash of values, but he does foresee the possibility of future new waves of open dissent and that these could be stimulated rather than eliminated by attempts to control science and scientists more closely. □

Robert Lewis is Lecturer in Economic History at the University of Exeter, UK.

Soviet technical intelligentsia

Julian Cooper

Technology and Society under Lenin and Stalin: Origins of the Soviet Technical Intelligentsia, 1917–1941. By Kendall E. Bailes. (Princeton University Press: Princeton, New Jersey, and London, 1978.) £20.10.

THE role of engineers and other technical specialists in a society in transition between capitalism and socialism is a question which, for understandable reasons, received little attention in the writings of Marx and Engels. In a rarely cited letter of 1890, however, Engels wrote:

> "Of course we still have insufficient technicians, agronomists, engineers, chemists, architects, etc., but if the worst comes to the worst we can buy them for ourselves, just as the capitalists do, and if some of them turn out to be traitors (as will certainly be the case in that society) they will be punished for the edification of the others, so that they will appreciate that it is not in their own interests to rob us any more. But with the exception of these specialists, and also the school teachers, we can very well do without the rest of the 'educated'. For example, the current strong influx into the Party of penpushers and students brings all kinds of trouble in its wake, unless these gentlemen are kept within proper limits".

Lenin, in the years preceding the October Revolution, also found such 'gentlemen' troublesome, but immediately after the successful winning of power the Bolsheviks had to face up to the problem of retaining the desperately needed skills of the technical specialists, the overwhelming majority of whom were unsympathetic or actively hostile to the Soviet power. In his pioneering study, Kendall Bailes, associate professor of history at the University of California at Irvine, is concerned with the fate of these engineers and technicians and the contradictory process by which a new technical intelligentsia, in the main loyal to Soviet society, was formed. The relationships between the technical intelligentsia and other social groups are

POLYMERIC DELIVERY SYSTEMS: Midland Macromolecular Monographs Volume 5
Edited by Robert J. Kostelnik

This graduate level volume contains 18 papers presented at the fifth symposium, held at the Midland Macromolecular Institute, Midland, Michigan, and will be of interest to research workers in not only polymer and physical chemistry, but also medical researchers.
320pp 1978 0 677 14940 4 £22.10

MOLECULAR BASIS OF TRANSITIONS AND RELAXATIONS: Midland Macromolecular Monographs Volume 4
Edited by Dale J. Meier
This symposium was organized to honour Raymond F. Boyer on his 65th birthday, and covered the selected field with speakers asked to present overviews of their topics, ranging from theory to mechanical and dielectric relaxational spectroscopy to relationships between molecular transitions and physical properties.
442pp 1978 0 677 11240 8 £29.60

A PERSPECTIVE OF PHYSICS Volume 2
Introduced and edited by Sir Rudolf Peierls

Following the highly-acclaimed first volume of this annual serial publication, Sir Rudolf Peierls, F.R.S., considers in this volume the advances in modern physics for the year 1977.
296pp 1978 0 677 12400 7 £16.70

Rock-Forming Minerals Volume 2A: Single-Chain Sillicates

Second edition
W A Deer, R A Howie and J Zussman

We are pleased to announce a new edition, in two parts, of Volume 2 of this well-known reference series. The book has been completely rewritten to take into account the enormous amount of research on minerals carried out in the fifteen years since it was first published.

This volume deals mainly with the pyroxene minerals, but also with pyroxenoids, sappirine and aenigmatite. The double-chain silicates will be covered in *Volume 2B* (available next year). Each mineral chapter contains sections on structure, chemistry, optical and physical properties, distinguishing features and paragenesis. The chapters are headed by tabulated mineral data and sketches showing optical orientation, and conclude with full references.

Like the first edition, this revision is destined to become a standard reference work.

Ecology of African Mammals

M J Delany and D C D Happold

Recent research has led to a much better understanding of African ecosystems and the adaptations, behaviour and physiology of African mammals. This authoritative book brings together much of this knowledge, drawing examples from animals as diverse as elephants, antelopes, rodents, primates and shrews. The emphasis throughout the book is on how different species live, survive and reproduce in the varied habitats of tropical Africa.

Ecology of African Mammals is generously illustrated and will be welcomed by all those studying mammalogy and tropical ecology. It will also be of interest and value to foresters and conservationists.

In the *Tropical Ecology* series

Longman

Circle No. 43 on Reader Enquiry Card.

explored and an assessment made of its place and role in the political system during the formative years of the modern Soviet state.

As Bailes lucidly relates, in the early years under Lenin's insistence and in the face of opposition within the Party the Bolsheviks did indeed 'buy' for themselves the services of the bourgeois technical specialists, both by ensuring them relatively privileged material conditions during the lean years of civil war and famine, and also by providing improved opportunities for applying their professional skills In the very first years of the revolution a number of important new applied research institutes were founded and many engineers, though unsympathetic to the regime, were involved in the drawing up of the famous GOELRO plan for electrification of 1920.

At this time, as Engels predicted, 'traitors' were punished for the edification of their colleagues. By this carrot and stick approach the Party succeeded in winning the majority of the old technical specialists to work for the Soviet power, and some forsook their political antipathy or neutrality and joined the Communist Party. From 1928 to the summer of 1931, at the time of the adoption and initial implementation of the ambitious first five-year plan and the associated struggle against the right-wing opposition led by Bukharin, a section of the old technical intelligentsia came under attack, accused of 'wrecking' activities. These events are described in detail by Bailes, who argues with originality and plausibility that the Party leadership around Stalin feared the growth of a 'technocracy' movement which, like its counterpart in the United States at that time, sought to elevate the engineers as a professional group to a position of political influence and power.

In order to break the country's dependence on technical skills without socialist commitment, the Party launched a large-scale programme for the education of a new generation of Soviet engineers, the majority of whom were of working class origin. Bailes devotes considerable attention to the formation of this new technical intelligentsia and chronicles its expansion and mounting influence during the 1930s. In the purges the technical specialists, like other professional groups, suffered greatly, although Bailes is probably correct in suggesting that engineers and technicians had a higher survival rate than, say, the industrial managers. Even after the worst waves of repression many representatives of the old technical intelligentsia continued to occupy posts of authority in industry and higher education. Before and during the purges Stalin and other Party leaders constantly stressed that specialists had to be politically conscious and committed, and it is notable that by 1937 there were almost 50,000 Party members with higher technical education, compared with a mere 138 graduate engineer Party members in 1928

The rapid economic and social development of the pre-War decade was accompanied by a radical transformation of the political status of the engineers they started as critical outsiders and ended as a significant group within the Party and government. Between 1939 and 1941 no less than 70% of new Party members came from the ranks of the administrative and technical intelligentsia. As Bailes observes, many of the members of the present-day Party Central Committee and Politbureau, including Brezhnev himself, are representatives of this new generation of technical specialists who embarked on their careers in the turbulent pre-War years.

In discussing the origins of the Soviet technical intelligentsia (throughout inelegantly and inaccurately termed the 'technostructure'), Bailes draws on an impressive range of sources, both Soviet and Western, and presents much new interesting material Rejecting both the totalitarian and the more recently fashionable interest groups models of Soviet politics, the author adopts a more flexible approach, placing greater emphasis on the interaction of social forces making for cohesion and conflict than is usual in discussions of the Soviet Union in the 1930s. This leads Bailes to analyse political developments between 1931 and 1937 in terms of a growing tension between the industrial managers and technical specialists and their spokesmen in the Party leadership on the one hand, and the group of 'Stalinists' (not satisfactorily defined) on the other, with the planning process as the focus of discord. But this interpretation, central to the author's discussion of the purges, is not wholly convincing The planning process is seen one-sidedly in terms of the setting of output targets, to the neglect of problems of the allocation of inputs, which at times produced quite different conflicts of interests. In general, the author's grasp of economic and, in particular, technical matters is not as sure as his understanding of the processes of social and political changes, although in analysing the latter a debatable definition of class is used, according to which manual and non-manual workers, including the entire technical intelligentsia, form two distinct classes

With a work of such impressive thoroughness and length it is perhaps unreasonable to point to omissions, but one would have welcomed more consideration of the substantive technical issues which were debated by the engineers, often with great passion, during the years of rapid industrialisation—for example, the relative merits of American mass-production engineering technology as opposed to the traditional Western European methods. There is also insufficient consideration of the important contribution of foreign technical specialists (over 9,000 were working in the USSR in the autumn of 1932) and a related tendency to divorce Soviet internal developments from events in the then increasingly hostile outside world: it could be argued, for example, that the moves in the summer of 1931 to improve relations with the old technical intelligentsia were not unconnected with the measures in May to reduce the level of reliance on foreign technical assistance.

Kendall Bailes has provided an important contribution to the steadily growing body of literature on the history of Soviet society which seeks to take a fresh approach based on serious original research, rejecting the crudities and prejudices sadly prevalent during the Cold War years ☐

History of integrated circuits

Andrew Holmes-Siedle

Revolution in Miniature: The History and Impact of Semiconductor Electronics. By E. Braun and S. MacDonald. Pp. 231. (Cambridge University Press: Cambridge and London, 1978.) £8.50.

"AN integrated circuit is a truly awe-inspiring achievement of human inventiveness". So say the authors of this book Those working on silicon technology, who know what effort and physical insight is packed into those minute structures, will not find it difficult to agree with this statement. For those not so privileged, the integrated circuit is likely to inspire puzzlement rather than awe. The structures concerned consist merely of microscopic modifications on the surface of a silicon chip. They usually lie sealed in anonymous little ceramic or plastic blocks and these themselves are commonly shut away inside the case of a calculator, television set or satellite. Hardly stirring stuff for the average man. How can one bring home to the layman the undoubted revolution which they are bringing about in industry and the home?

The authors of this book, who are members of the Technology Policy Unit at the University of Aston in Birmingham, have made an attempt to view the history of the integrated circuit as a whole and bring a little of its flavour across to the intelligent reader. They have tried to add a little life to that formidable array of technological fact in several ways: first, by conducting interviews with some of the engineers and physicists involved and quoting parts verbatim—this is very successful; and second, by adopting a loose form of comment which one can only call journalese ("for a fraction of the cost of one week's housekeeping, one can have access to any number's square root"). The results are sometimes fascinating but often baffling, especially when sweeping statements are made without support and the references, when one turns to them, are more often to *Business Week* than to the original literature. Perhaps this is the style of theses in technology policy but it is galling to a serious reader who is reaching for his pencil in anticipation of an original historical reference which he can follow up. Perhaps this is asking too much, however, of a book which the authors direct to the "intelligent lay-reader" Nevertheless, there are at least 600 references given. This makes the work a curious mixture of academic study and "pop history".

The opening chapters of the book are well worth reading, being an enjoyable and brief account of the history of the invention of the transistor, with suitable comments on the influence of science, commerce, the military and the upheavals caused by World War II. The hothouse atmosphere of Bell Laboratories is well created and the subsequent commercial spread of the transistor is dealt with in fairly conventional narrative form. The authors avoid any diversions into technical explanation, possibly leaving a little too much for the general reader to pick up elsewhere. It is noteworthy that the only line-drawings in this book are financial charts. How many scientists could write a book without recourse to technical sketches?

In this section, historical balance is lacking in at least one respect: the invention of the metal-oxide-semiconductor (MOS) transistor by Hofstein in 1962 is passed over too lightly. Although the events of the late 1940s at Bell are exhaustively documented (at least 60 references are quoted including dozens of interviews), the inventor of the MOS device is neither named nor interviewed. The term "MOS" is only mentioned a few times in the whole book and this can be viewed as a serious lack of balance, because the ability to manufacture large-scale integrated circuits cheaply from MOS elements has been the main driving force of the revolutions of the 1970s. It is also predicted by others that MOS circuits will dominate microelectronics in the 1980s. In fact, the history of the Intel company, the manufacturer of the first MOS microprocessor, is probably as important as that of Bell, but it is not described except as part of a more general description of Silicon Valley.

The later chapters of the book bring the reader up to date concerning the invention of the integrated circuit and the immense expansion of uses which came with this step. More space is given in this section to business considerations, such as figures for the growth of markets and the pricing of components. It is likely that the technologist will find this more interesting than will the lay-reader It is also here that the very speed of technological progress which all commentators emphasise seems already to have dated the book. Electronic games, Viewdata and the charge-coupled device are not mentioned, and the word "microprocessor" is not even listed in the index. The splendid compatibility between the integrated circuit and the satellite is not noted and Space is, in fact, only mentioned as part of an "awesome list" of weapons. These, the authors point out, are "packed with electronics from top to bottom". It is in this section that oral history techniques come into their own The interviews give the right tang of "entrepreneurialism" (*sic*) flavoured with physics which characterises the microelectronics industry in the USA. The authors should certainly persevere with this method.

The concluding chapter presents "Reflections of an Electronic Age". From authors who have performed a social analysis of the past three decades of electronics, one expects some penetrating statements covering future applications and the future cultural influences of microelectronics. This the authors attempt to do but the statements too often dissolve into generalisations that are far from penetrating. It is not too much to ask even a popular history book to be penetrating.

We badly need help in understanding the wide social impact of microelectronics. This book may help many by its factual survey but, for this reader, it provided no more than the faintest glimmer of fresh understanding. ☐

What use is astronomy?

A. J. Meadows

Man and the Stars. By Hanbury Brown Pp.182. (Oxford University Press/Clarendon: Oxford and New York, 1978) £5.95, $14 95.

PROFESSOR Hanbury Brown explains in the preface how he came to write this book:

> For fifteen years I have run an astronomical observatory in the Australian Bush . . . In that time I must have shown the place to thousands of visitors and tried to explain what we were doing and why . . However, there was one particular question which always worried me because I couldn't answer it satisfactorily in the time available, usually only a few minutes before the coach left. It was often asked tentatively, away from the main group of visitors, as though it might be silly or, perhaps, impolite It was always the same basic question—'This work may be competent and interesting, but is it any use?'".
>
> I found it comparatively easy, given a few minutes, to persuade people that our work was relevant to the general study of astronomy, but I have never been able to abbreviate, to my satisfaction, the arguments that astronomy is an integral part of science and that science is an essential part of our civilization. And so, as the coaches vanished in a cloud of red dust, I was often left wondering what the visitors really thought of our observatory. Many of them, I suspect, felt much the same as they would have done after a tour of a monastery—interesting maybe, but a useless way to spend one's life!

What this book sets out to do, therefore, is to try and sketch out Professor Hanbury Brown's own answer to the question—what use is astronomy? It is a question that should engage the attention not simply of astronomers, but of all pure scientists. Most of us have our salaries, our accommodation and our equipment provided by the state—that is, ultimately, by everybody else in the community How can we justify this expenditure to them?

Here, for astronomy, we are offered answers under five headings: stars and the calendar, stars and time, stars and navigation; stars and science, stars and man. (I am not altogether clear why the title is *Man and the Stars*, even though the chapter headings run in the opposite direction Perhaps it is to remind us that astronomy could not be practised if either of the two components 'man' or 'stars' were missing.)

Books From Every Branch of Science

BIOLOGY

Physiology of Membrane Disorders
edited by **Thomas E. Andreoli, M.D., Joseph F. Hoffman, Ph.D.,** and **Darrell D. Fanestil, M.D.**
approx. 1,100 pp., illus., 1978, $90.00/£47.25

The Biology of Aging
edited by **John A. Behnke, Caleb E. Finch,** and **Gairdner B. Moment**
400 pp., illus., 1978, $22.74/£11.94

The Photosynthetic Bacteria
edited by **Roderick K. Clayton** and **William R. Sistrom**
approx. 935 pp., illus., 1978, $102.00/£53.55

Second Edition

THE EARTH'S TECTONOSPHERE

ITS PAST DEVELOPMENT AND PRESENT BEHAVIOUR

J. H. TATSCH

We are pleased to announce that the first (1972) edition of *The Earth's Tectonosphere* has been completely revised. The new edition updates the results of our continuing research to determine the most probable geometrical, mechanical, thermal, and chemical aspects of the origin, evolution, and present behaviour of the Earth's upper 1000 kilometers. Included are about 80 of John C. Holden's inimitable drawings.

More specifically, this book is a multiple-hypothesis analysis of the development of the Earth's internal structure during the past 4.6 billion years, of how this deep structure has controlled the Earth's internal behaviour since the Earth began, and of why the surficial geophenomena and features are manifestations of that internal behaviour.

Chapter headings: 1, The origin of the solar system; 2, The Earth-Moon system; 3, The Tectonospheric Earth Model, 4, The Earth as a planet; 5, The crust of the Earth, 6, The tectonosphere; 7, The orogenic-cratonic structure of the continents, 8, The Earth's deep seismicity; 9, Global patterns of geothermal activity, 10, Intrusive and extrusive activity; 11, Morphology of the Earth; 12, Mountain building, 13, The Earth's gravity field; 14, Geomagnetism and polarity reversals, 15, Continents and oceans, 16, Sea-floor spreading; 17, Continental drift and polar wandering; 18, Plate tectonics and related omni-ductive processes; 19, Asteroids, meteorites, and tektites; 20, The Integrated Earth and its future.

The Tectonospheric Earth Model concept, developed in the first edition and repeated in this edition, differs essentially from other global-tectonics concepts in two salient respects: (1) it embodies the geometrical, mechanical, thermal, and chemical aspects of a driving mechanism that has existed during the entire 4.6 billion years that the Earth is believed to have been in existence; and (2) it encompasses the Earth's spatio-temporal framework to a depth of 1000 km during these 4.6 billion years.

The second edition attempts to show, as did the first, how these two differences permit a more meaningful interpretation of the origin, evolution, and present characteristics of the Earth's behaviour than is possible through other global-tectonics concepts This pertains not only to the Earth's lithospheric plates but to all plates, blocks, and other forms of material that have evolved within the upper 1000 km of the Earth during the past 4.6 billion years.

The Tectonospheric Earth Model has been used as the basis for 10 correlative follow-on books· *Mineral Deposits* (1973), *The Moon* (1974), *Petroleum Deposits* (1974), *Copper Deposits* (1975), *Gold Deposits* (1975), *Uranium Deposits* (1976), *Geothermal Deposits* (1976), *Earthquakes* (1977), *Coal Deposits* (in press), and *Iron Deposits* (in preparation).

Available directly from the publisher or through book dealers in all parts of the world. Hard cover, 6×9 inches, 468 pages. Table of contents, line drawings, maps, bibliography, index. $30 LC: 74-78917. ISBN 0-912890-03-7. 1977.

Tatsch Associates

120 THUNDER ROAD
SUDBURY, MASSACHUSETTS 01776
U.S.A.

Circle No 45 on Reader Enquiry Card.

The purpose behind each of these headings is to emphasise how the development of astronomy and the growth of other human activities and thought interact. From this viewpoint, the first three chapters should really be read together They recount how man down the centuries has used astronomy as a means of fixing his position in time and space. This ability is obviously fundamental to the existence of civilisation. Agriculture and religion needed a viable calendar; organisation of the working day required good time-keeping, travel and, therefore, commerce over any distance demanded accurate navigation. The fourth chapter tackles a different aspect of astronomy: its role in the advancement of basic science and, in particular, physics. The final chapter looks at the much more diffuse and difficult question of the influence astronomy has had on the way we interpret and experience the world around us.

We are provided with a well written and lucidly argued case for the importance of astronomy, but I feel that somehow, for much of the book, the author actually avoids the main point. The real question is not whether astronomy had immediate relevance to everyday life in times past, but whether it has such relevance today. Already in the eighteenth century, astronomy was ceasing to be of practical concern to more than a few people. Thus, the astronomer in Samuel Johnson's *Rasselas* says that he has devoted his life to the wrong subject, because the knowledge he has acquired is of little use to mankind. Of course, astronomy still has some practical uses today. Some years ago I was telephoned by a major British company, who required a quick astronomical method of checking some alignments in their surveying operations. I suggested a method which was adopted—so, is this not a clear example of a practical use of astronomy? (As I forgot to ask for a consultancy fee, it unfortunately does not simultaneously demonstrate the practical use of astronomers.) But the concepts behind my proposal had been known for centuries. The problem is that the ideas most astronomers are concerned with today seldom, if ever, have relevance to everyday affairs. I find the counter-examples that Professor Hanbury Brown suggests distinctly unconvincing. For example, he mentions the importance of astronomy for space navigation. But this simply raises the question—what is the current utility of space navigation? The only space activities which certainly have a value for everyday life are those concerned with Earth applications, and the satellites involved in these hardly require space navigation.

It is worth laying considerable stress on astronomy's lack of immediate utility because it distinguishes astronomy from other major divisions of science. The others can all claim to have something to contribute towards the material interests of human beings; but astronomy has declined over the past few centuries from being a highly useful subject to being almost useless. Nor has astronomy provided much basic information to other areas of science. Rather, throughout the twentieth century, astronomy has taken more from other disciplines than it has given to them. Yet astronomical research has not declined over this period. On the contrary, state support for astronomy is now provided on a larger scale throughout the world than would have been imagined possible a century ago.

If we seek a reason for this funding it must derive then from the importance of astronomy for our view of the world. This has continued to be recognised long after the practical value of astronomy declined. Thomas Huxley, presumably unbiassed as a biologist, claimed that astronomy is the science "which of all sciences has filled men's minds with general ideas of a character most foreign to their daily experience, and has, more than any other, rendered it impossible for them to accept the beliefs of their fathers". As long as this sort of claim can be made for astronomy, or for any other branch of pure science, it can surely hope to receive financial support. But there is a proviso. For astronomy to affect our view of the world, its advances must be made available and understandable to people who are not astronomers. Professor Hanbury Brown therefore concludes his book with a plea for the proper popularisation of science. He is to be congratulated on practising what he preaches in such a readable way. □

A. J. Meadows is Professor and Head of the Department of Astronomy and History of Science at the University of Leicester, UK.

Technological day-dreams

R. L. F. Boyd

Spaceships of the Mind. By Nigel Calder. Pp.144. (British Broadcasting Corporation: London; Viking: New York, 1978.) £6.50; $14.95.

WHEN a project in space science or technology is undertaken in the real world, the lives and reputations of real people are at risk. Real public money is spent for which there are many competing calls: many of them are less worthy, but some may have stronger claims on resources. Those involved in the decisions and execution of the projects are usually alert to the glare of publicity surrounding their activities and the incalculable consequences of failure. The long road to realisation involves a succession of studies followed by detailed scrutiny and by battles for authority to proceed, which may be lost or won. A typical sequence involves Mission Definition, Pre-feasibility Study, Feasibility Study. These are sometimes called Phase A, may cost several per cent of the final project and usually have a significantly less than even chance of surviving for further work.

The next phase — Phase B — the Design Definition, involves a hard and disciplined engineering grind in which 'state-of-the-art' parts of the project are carried through to a point of readiness when a "metal-cutting" realisation of the project — Phase C — can be or perhaps cannot be entered upon. Any parts of the project requiring research and/or development will have been identified, assessed and costed. Some limited experimental work such as determining the emissivity/absorptivity of a particular surface material or its deterioration by solar ultraviolet radiation may have been undertaken. Exceptionally the procurement of long lead items not representing a major part of the cost may have been put in hand. By this time 10% or so of the total cost to launch will have been committed. That cost will have been established to within about 10% and a decision whether or not to proceed must be taken.

Phase C, the production phase, is a long agony of finding out how difficult things are in practice; fighting specification deviations (one firm supplied me with stainless steel screws made, we discovered in the final magnetic survey of an Orbiting Solar Observatory, from "the nearest alloy to the one specified which was available"; they were excellent in all respects except the one that mattered most; they were magnetic); fighting safety problems real and in the minds of ill informed safety officers; testing, going back to the drawing board, re-testing, accepting or rejecting compromises and so on.

Spaceships of the Mind make no such demands on reality but like other hallucinations are probably best regarded as a (bad?) dream. I would have settled for science fiction but the necessary imagination and drama are absent. Calder's previous book *The Key to the Universe* (but not the television production) was, in my view, a brilliant service to science. It showed to the intelligent layman such coherence in our understanding of the mystery of being as could be shown and my only quarrel was with the suggestion that there is likely to be a key to so much that could be grasped in any ultimate way by the limited system of neurones in the human brain.

Unfortunately this latest book (mainly about space colonisation) fails to convey the nature of the process by which technical problems are specified and solved, thus obscuring the gap between the dream and reality. I have theoretical astrophysicists on my staff but when I want to know what can or cannot be done for a projected payload I go to my engineers.

Calder goes to distinguished scientists of which the late J. D. Bernal is the prototype. He talked to John Lewis a cosmic chemist, to Freeman Dyson an eminent theoretical physicist, to Sol Spiegelman a distinguished molecular biologist, to Stephen Cheston an historian, and to many others of comparable distinction and similar qualifications. He did talk to some engineers. The late Val Cleaver was one of the greatest, and he was inclined to think that a "distinguished physicist" like O'Neill "ought to know better" than to suggest space colonisation on a time scale of decades. Theordore Taylor was a rather different engineer whose ideas entitled by Calder "The Santa Claus Machine" seem to me as far from any realistic materials science as that childhood myth. I cannot believe that justice(?) has been done to this former Princeton professor. I feel the same about Henry Kolm and his "mass driver"—an electromagnetic gun for ejecting pieces of asteroids or the Moon or what-have-you either for reaction propulsion or as a kind of space parcel post. These engineering essays carry no conviction because they are presented with no calculations. This is a disservice. Above all else, physical science and engineering is numerate. If this lesson were learnt at school we would be spared the correspondence from cranks who invent this or discover the explanation of that, when a sum on a postage stamp would expose the nonsense.

On the credit side, Calder does devote some attention to the Earth which in all conscience needs it more surely than the rest of the galaxy; he shows some recognition that ethical problems of humanity may overwhelm the day-dreams and he makes it clear that his sample of prophets has been strongly selected to "test the hypothesis that recent advances in scientific knowledge ought to have stirred constructive thoughts". The hypothesis is verified. What other thoughts will be stirred for good or ill I cannot guess. If you are only going to buy one book buy *The Key to the Universe*. If you are going to buy two let me commend a story Dingle once told before a lecture by Eddington on his more recondite and less certain speculations. A man went into a restaurant and asked for a boiled egg and a kind word. The waitress brought the egg and turned to leave the table. He reminded her he wanted a kind word. "Don't eat it", she said. ☐

Rebel without a cause

Michael Rowan-Robinson

Scientists Confront Velikovsky. Edited by Donald Goldsmith. (Cornell University Press: Ithaca, New York, and London, 1978.) $8.95; £5.95. *Velikovsky and Establishment Science.* Edited by L. M. Greenberg. (Kronos: Glassboro, New Jersey, 1978.) $9.95.

IN 1950 a remarkable book by a Russian born psychiatrist, Immanuel Velikovsky, who had lived in the US since 1939, was published. The book, *Worlds in Collision*, argued that the biblical account of the Israelites' flight from Egypt, together with numerous other ancient texts from cultures all over the world, carried the record of great natural catastrophes. Venus, ejected as a comet from the planet Jupiter, passed close to the Earth, causing earthquakes, volcanoes, floods and plagues, then dislodged Mars from its orbit onto a near collision course with Earth, before settling in its present circular orbit. The book aroused fury amongst certain members of the astronomical establishment. Efforts were made to prevent publication of the book, and to persuade astronomers to boycott the publishers.

Gradually the furore subsided. The book has been popular with the public but has for the most part been ignored by astronomers. Velikovsky is an excellent writer and if he had taken the trouble to learn what is known in astronomy and geophysics, he would have made a wonderful populariser of the field. As it is the book is of little scientific interest. None of the ideas are developed in any quantitative detail. The "predictions" are of the type: Venus is hot, Jupiter will be "a source of radio noises", the polar caps of Mars are "of the nature of carbon", argon and neon will be present on Mars "in rich amounts". Velikovsky and his supporters make great play of the cases where these "predictions" fit subsequent observations, but no effort is made to confront the theory as a whole with what is known.

In the early 1970s amid the growing popular interest, particularly in the US, in offbeat ideas and cults like parapsychology, the occult, astrology, and UFOs, Velikovsky became something of a guru. Two publications, *Pensée* and *Kronos* were devoted to his ideas. The young and rebellious flocked to his banner. Once again the establishment became alarmed. At the February 1974 meeting of the AAAS in San Francisco, a symposium was held at which four scientists tried to confront Velikovsky with the brick wall of facts which his theory must run into. One eye-witness told me he felt sorry for the way this old man was being utterly demolished by these arguments. Yet in his reply, Velikovsky steered his way round the wall to the satisfaction of himself and his vocal supporters.

It is unfortunate that *Scientists confront Velikovsky* contains only the arguments against Velikovsky, for it reads like Hamlet without the Prince. Velikovsky's contributions, together with nine other articles by his supporters, appear in a separate book, *Velikovsky and Establishment Science*. The reason for this fragmentation of what ought to have been the *Velikovsky Symposium Proceedings* is that Velikovsky asked for more space to answer his tormentors than the editor was willing to allow. To me this seems a piece of unnecessary pettiness. In the event Velikovsky's contributions amount to rather fewer words than those of his principal inquisitor, Carl Sagan.

It has to be said that Velikovsky faced his ordeal with considerable dignity, both at the symposium itself and in his published articles. This is not always true of those whom the scientific establishment rejects and despises. In some, like Herbert Dingle in *Science at the Crossroads*, the bitterness of their treatment becomes more important than the scientific case they are trying to make. This type of attitude is prevalent in many of Velikovsky's supporters. The main object of their hate is Sagan and they have worked very hard to ferret his more eccentric speculations out of the literature, with some success. Why should Sagan be allowed to speculate about life on Mars, extraterrestial civilisations and "galumping beasts" out there, and then ridicule

MAN AND MAMMALS

Toward a Biology of Form

Wolfgang Schad

This textbook will delight and instruct lay readers, and should set before serious students of biology not only a host of problems that deserve further inquiry, but valid clues to the most fruitful method for such inquiry. It should be read in homes, in high schools and colleges, as well as by professional students of zoology and animal behaviour. Its methods and conclusions are an important step towards the holistic biology that will give us a better perspective than we have at present on man's place in the natural order and will open the way to auspicious new beginnings in medicine, agriculture, education and animal husbandry.

SENSITIVE CHAOS

The Creation of Flowing Forms in Water and Air

Theodor Schwenk with a foreword
by Jacques Y. Cousteau

Ever in demand, this unique book on the natural behaviour of air and water would be significant for its magnificent series of nearly 100 photographs alone. Yet it is more than a delight and fascination to the eye. In an age when pollution of both of these elements is of prime concern to mankind, it is important that what has been called 'the first authentic treatise on the phenomena of Water and Air' should present them as the *living element* they are, not simply as indispensable raw materials. A book for all interested in the wonders of the world we inhabit and the forces that form it.

ANTHROPOSOPHICAL MEDICINE

An Extension of the Art of Healing

Victor Bott, M.D.

The Art of Healing has always reflected man's ideas of his own nature. Modern medicine has thus been strongly influenced by the natural scientific thought of the nineteenth century. It tends to look upon the human organism as a sort of test tube in which certain processes analogous to laboratory experiments take place. But the practitioner called to his patient's bedside knows that this way of looking at things is inadequate, in the face of day to day reality. Here he experiences a half-conscious lack of satisfaction and a feeling of inadequacy for his task. Perhaps we can consider this as indicating that our scientific picture of man is incomplete. Thus it would be helpful to recreate this picture and widen our conception of the human being, so as to create an art of healing more in harmony with tangible human reality – a medicine really able to encompass that reality.

translated by F.L. Wheaton and G. Douch

The Wykeham Series

New and forthcoming titles

GALAXIES: STRUCTURE AND EVOLUTION
R. J. Tayler
The present structure of galaxies and their past life history are presented in general terms. Most of the detailed discussions are of our own galaxy.
0 85109 670 0 (Paper) £4.50 net
0 85109 680 8 (Cloth) £7.50 net
200 pages 216 × 139mm

SEX DETERMINATION AND SEXUAL DIMORPHISM IN MAMMALS
A. Glucksmann
This monograph highlights the differences between the sexes in the structure and function of mammalian organs and the bearing they have on reactions to exogenous influences.
0 85109 800 2 (Paper) Approx. £4.00
170 pages 216 × 139mm

RADIOCHEMISTRY: THEORY AND EXPERIMENT
T. A. H. Peacocke
Radioactivity is explained in relation to chemistry and its applications; early experiments, laws and techniques are examined.
0 85109 690 5 (Paper) Approx. £5.00
260 pages 216 × 139mm

MAN-MADE DISASTERS
B. A. Turner
Some of the common features of accident situations—social defects and human error—are discussed, both in general terms and in relation to specific disasters.
0 85109 750 2 (Paper) Approx. £4.50
256 pages 216 × 139mm

RADIOACTIVITY AND ITS SOCIAL CONTEXT
E. N. Jenkins
This book surveys the development of theories and applications of radioactivity and provides an objective background to the nuclear power debate.
0 85109 730 8 (Paper) Approx. £4.00
198 pages 216 × 139mm

IMAGES: A UNIFIED VIEW OF DIFFRACTION AND IMAGE FORMATION
C. A. Taylor
This book demonstrates how diffraction and imaging processes, no matter what radiation is used, have a common underlying principle. The approach is largely visual, using many original photographs.

A critical examination of the evidence points to Teilhard de Chardin as the Piltdown hoaxer and shows that other 'missing links' are equally dubious.

APE-MEN

Fact or Fallacy? M. Bowden

Summary of Contents

PILTDOWN. The considerable body of little publicized evidence which indicates that the most likely suspect for the forgery is Teilhard de Chardin S.J.

APE-MEN 'EVIDENCE'. The very speculative nature of the evidence for 'ape-men', and the presumptuous way in which this is presented.

EARLY HOMO SAPIENS. Their existence in deeper strata than those of 'ape-men'. The superficial reasons given by the experts for their rejection.

PEKIN MAN. A 25 ft. high ash heap, bone tools and other evidence of human habitation of the site virtually suppressed by the experts in China. Details of the discovery of human skeletons delayed for five years. Ape-like skulls reconstructed with human features.

JAVA MAN. Dubois's concealment of human skulls for thirty years. The faking of scientific illustrations by Dubois's supporter, Professor Haeckel. The strange circumstances of the discovery of further fossil 'evidence' of Java man.

NEANDERTHAL MAN. The evidence that these were true men suffering from rickets, arthritis and syphilis.

THE AFRICAN APE-'MEN'. The admission by several experts that all these fossils are simply apes with no real human features.

RAMA PITHECUS. Fossil evidence only consists of jaws and teeth. L. S. B. Leakeys devastating letter regarding their classification.

"1470 MAN". Probably a small human skull, as human leg bones found in same stratum. Embarrassing first radiometric dating which experts ignored.

CONCLUSION. An examination of the original reports on the 'ape-men' fossil fragments highlights the questionable circumstances of their discovery, and shows that the 'missing links' are unscientific conjectures.

It becomes clear that not one of the many fossils discovered can be accepted as providing any evidence for links between man and the animal kingdom.

8½"x5½"x⅝". 200 pages. 55 illust. Bibliography. Indexed. Stitch bound. Four colour cover. ISBN 0 9506042 08. £3.30 (post free).

Velikovsky's notion of fly larvae in the tails of comets? More generally, why is it OK for Hoyle and Wickramasinghe to speculate about world-wide epidemics brought by cometary dust, and for Sagan to speculate about the evolution of human intelligence, but not OK for Velikovsky to speculate about astronomy?

The crucial point, to be borne in mind by all weekend cosmologists, is that a demonstrated awareness of what is known and what current ideas are is a prerequisite to being listened to seriously by scientists. The more you have demonstrated that you know, the more your speculations will be listened to. If you are Hoyle or Ryle, your views on energy production will be listened to with sympathy. If you are Einstein, your views will even be sought on the international political scene.

How good a demolition job did Sagan *et al.* do on Velikovskianism? Although some of them, particularly Sagan and Huber, obviously put a lot of work into preparing their contributions, the result is not altogether satisfying Rather too many weak arguments, niggling at peripheral issues, appear in these pages The most solidly argued case is that of David Morrison (not actually a symposium participant) who doesn't bother to chase every hare Velikovsky starts. He concentrates on the solid bedrock of facts that Velikovsky is inconsistent with; the huge difference in composition between Venus and Jupiter, and between the allegedly interchanged atmospheres of Venus, Mars and Earth; the evidence that the era of major cratering on Mercury and the moon ended 4×10^9 yr ago, rather than 3,000 yr ago as Velikosky believes; the evidence that the moon has never been molten, so that craters cannot have formed by bubbling, the evidence from the craters of Venus that it cannot have been torn from Jupiter recently, and the absence of evidence for residual excess heat in Venus and Mars

Sagan has additional arguments involving the difficulty of ejecting Venus from Jupiter; the low probability of cometary encounters with Earth, the difficulty of restarting the Earth's rotation once it has been stopped; the problem of circularising the orbit of Venus; and the total mass of manna required to feed the children of Israel for 40 years. Apart from the manna question, which I find a bit of a red herring, these difficulties do not seem to me insuperable given the initial catastrophist framework Similarly Huber's demonstration that the ancient Babylonian Ammizaduga cuneiform tablets are consistent with the modern orbit of Venus is fascinating, but hardly compelling evidence against Veliovsky in the light of the data massage, not to say downright resuscitation, required.

The arguments of *'Scientists confront Velikovsky'*, though of variable quality, are overwhelmingly strong enough in totality to reject Velikovsky's scenario. Why then do the young and rebellious, not to mention a few professors of history, philosophy and anthropology, follow Velikovsky? Asimov, in an entertaining forward to the anti-Velikovsky book, suggests: "Supply the public with something amusing, that sounds scholarly, and that supports an idea it wants to believe (in this case the literal truth of the Bible), and surely you need nothing more."

Does anything then remain of Velikovskianism? What is the basic core of his idea? That a comet passed near the Earth in classical times causing chaos. Suppose a massive long period comet were first noticed towards Jupiter and then appeared as a bright evening or mornning star before brushing past the Earth Would not the ancient myths then speak of Venus, daughter of Jupiter, bringing disaster? Stripping Velikovsky's scenario of the direct association with Venus and Jupiter eliminates almost all the refutations offered against him It also, of course, eliminates almost all Velikovsky's astronomical "predictions". What would remain is his evidence from the ancient texts, easily the most interesting part of *Worlds in Collision*. Can such a scenario be refuted? And if it were one day proved correct, would we say that this curmudgeonly old rebel had a cause after all? ☐

Michael Rowan-Robinson is Lecturer in Applied Mathematics at Queen Mary College, University of London and is currently on study leave at the Radio Astronomy Laboratory, University of California, Berkeley, California

Ptolemy in the dock

D. T. Whiteside

The Crime of Claudius Ptolemy By R. Newton. Pp.411. (Johns Hopkins University Press Baltimore and London, 1978.) £15.75.

"THIS is the story of a scientific crime", begins the author, "committed by a scientist against his fellow scientists, a betrayal of the ethics and integrity of his profession that has forever deprived mankind of fundamental information about an important area of astronomy and history" And he concludes his summing-up for the prosecution "All of his own observations that Ptolemy uses in the *Syntaxis* are fraudulent, so far as we can test them . His work is riddled with theoretical errors and with failures of comprehension . His models of the moon and Mercury conflict violently with elementary observation . . The *Syntaxis* has done more damage to astronomy than any other work ever written, and astronomy would be better off if it had never existed " In between, for almost four hundred pages, comes a relentless attack on the character and achievement of "the most successful fraud in the history of science" such as would do any cross-examining QC in the Old Bailey proud

Shifty-faced Ptolemy in the dock is found morally guilty of systematically falsifying past records for his own ends and left with only the odd one of his own observations of the heavenly motions which "may be genuine" (never, of course, the charity of "may be false".) He is not allowed credit even for his bissextile equant model of circular motion for the outer planets and Venus—that on which alone a near-perfect theory of all the solar planets may be founded, and which even Newton must allow to be "indeed . . a contribution to astronomy" "There is no evidence", he thunders, "that [its discovery] was made by him . . and Ptolemy lessens its value considerably by his inaccurate use of it" What a dullard lot succeeding astronomers have been—Copernicus especially (on whose debilities Newton is almost equally severe) —never for the best part of the next two millennia to have suspected any of this! And the wise juror waits patiently for the counsel for the defence to present his counter-case

From Newton he will get barely a glimmer of what that might be. Nor is here, in a short review, the place to specify with full subtlety and technicality of argument how time and again he fails to set out fairly the difficulties, theoretical and observational, which Ptolemy had to face in creating his synthesis, imperfect as it was, of existing astronomical knowledge—this through a previous analysis of data, 'truly' reduced from observed phenomena or confected *ad hoc* as they might severally have been, at which we can for the most part make only reasoned conjecture by re-analysing the finished synthesis itself as we alone have it

The modern fast computer allows us, it is true, freely to apply one powerful independent touchstone as to how the Sun, the Moon and the night sky would have appeared to the ancient observer (if we make certain minimal, seemingly well-founded, assumptions about the stability of the 'fixed' stars and the unchanged basic motions, secular and periodic, of the Sun, Moon and planets over the past several thousand years): that of extrapolating back from our modern accepted theories of such apparent motion. And on this test Newton bases the numerous charges of fraudulence in observation which he hurls at Ptolemy. Yet one must be very careful in interpreting divergences between 'observed' values and the predicted past event as it 'must' have been seen.

Modern theories are too exact for the historian's purpose, too well corrected for all manner of disturbing factors to afford a proper basis of comparison. Moesgaard and others have indicated that many of the past recorded sightings (those of lunar eclipses above all, on which depended in classical times all precise geometrical modellings of the Moon's motion) were themselves available to Ptolemy in a version already reduced to norm according to a variety of simple interpretative models about which he had no sure knowledge. And so to some degree it was no sin for him to hone their roughnesses. As for the raw observations themselves, there is no need to lay heavy stress on the gross inaccuracies and imprecisions which beset all sightings by the naked eye using only the most primitive of mechanical aids: at best the Greek astronomers could call on the help of an armillary sphere and a calibrated ring-dial ('astrolabe'), and their only exact means of timing was to use the diurnal motion of the Earth in shooting the Sun and the stars.

All of this Newton takes into account, though without emphasising the size of the errors—15′ of arc is nothing—which swiftly agglomerate. There are other less obvious sources of systematic error in taking sightings from our moving Earth which he does not mention at all, such as aberration, and above all atmospheric refraction and—complementary to this as it was measured—the observer's horizontal parallax. (In the late sixteenth century Brahe, the first to give tables for aerial refraction, still set upon the parallax a maximum value of 3′, some 20 times too large; and Ptolemy must have made reduction to the Sun by one much greater than this.)

When Mercury was only ever glimpsed near to maximum elongation, around dawn or dusk inevitably when the incoming light ray was bent up to 40′ from straight, we ought perhaps to admire Ptolemy for his bravery in putting his head on the chopping block with any attempted model of the apparent motion of that highly eccentric and perturbed closest satellite of the Sun. And who in honesty can be harsh with him for not more exactly predicting the orbit and changing apparent size of our own Moon when the problem defeated the combined efforts of all—even Newton's seventeenth-century surnamesake (who blandly changed the sign of one inequality in his lunar theory when it suited him)—before Euler and Mayer only two centuries ago?

Claudius Ptolemy

From an engraving by De Brij, about 1648

Not to say that Ptolemy's crank mechanisms for duplicating the motions of both these bodies do not, in their structure as well as their given parameters, rest on readily shakeable foundations. Gingerich, and Delambre long before him, have already shown us some of Ptolemy's eye-deceiving Potemkinist fabrications here. And Newton evinces all the puritanical zeal of the determined iconoclast in endeavouring to prove in the body of his present book that no more depth of reality underlies the rest of the *Syntaxis;* that this "Almagest" is the "greatest" only in the scale and elaborateness of its astronomical *trompe-l'oeil.* In his pages, to be fair, anyone with a passably numerate intelligence and a reasonable degree of historical understanding—this is not a book for the beginner, whatever Newton may say—will find much of the fine web of his explanatory analyses and reconstructions of Ptolemy's mode of thought and composition extremely persuasive, if not everywhere wholly convincing. Again, would there were room here to say more. It makes a good companion to Pedersen's recent exegesis from a different, more conservative viewpoint in his *Survey of the Almagest,* and to the wider precisions of Neugebauer's *History of Ancient Mathematical Astronomy.* A pity that Newton does not write his controversial account of the *Syntaxis* with a little more of their calmness and humility. One grows weary with the rantings of a pulpit-thumper who interminably moralises and chastises.

In the final count I remain unclear as to exactly what heinous 'crime' Ptolemy here stands charged with Surely not mere manufacture of evidence in the face of modern canons of scientific propriety, or 'improving' existing data to give a better fit with his preferred structurings of the observable phenomenal reality? Let one look to the working papers of Kepler or Newton (Isaac) in the seventeenth century and see how innocent and amateurish Ptolemy's efforts to round out and confect empirical data were, even if all that is here alleged be true. And if his fabrications, such as they might have been, were indeed a gigantic confidence trick which deceived astronomers for the next millennium and a half and more, is it not that they were knowingly led to believe the myth of his supremacy? Granted that Ptolemy's model of Mercury's orbit makes such a poor fit with what of it can be glimpsed by the naked eye even of an Earth-bound observer, why did the highly competent Arabic astronomers al-Shirazi and his pupil al-Shatir content themselves with so minimal a reshaping of it, one all but exactly preserving Ptolemy's lines of sighting? Yet more astonishing, how was it that Copernicus should in Book 5 of his *De Revolutionibus,* that clarion call to heliocentric 'revolution' as it is so often mistakenly made out to be, timidly settle for parroting al-Shatir's version (as who will now gainsay) of Ptolemy's theory of that planet's motion, one in which the Sun is as ever in motion round the Earth (and cannot be made to stand still in any version of it)? The history of the impact of Ptolemy's *Syntaxis* upon succeeding centuries is a deal more subtle and convoluted than any simple 'Newtonian' view of it as poor theory shabbily propped up by invented observational data, and the whole fraudulently presented to posterity as well-founded celestial science in classical hypothetico-deductive mould can more than start to explain.

If one suspends disbelief at certain passages in it, Newton's book makes an excellent read, but it is only the beginning of a serious estimate of Ptolemy's achievement, frauds and all. ☐

FRENCH NATIONAL INSTITUTE OF HEALTH AND MEDICAL RESEARCH

INSERM SYMPOSIA 1977-1978

Vol. 69 EARLY PROTEINS OF ONCOGENIC DNA VIRUSES

Edited by: P. May, R. Monier, R. Weil
416 pages/70 French francs/18 US dollars
Structure and genetics of the early region of SV40 and polyoma viruses; Isolation and identification of early proteins of oncogenic DNA viruses; Expression of early functions of oncogenic DNA viruses; Relation of T-antigens to parameters of cell transformation; Transformation by oncogenic RNA viruses.

Vol. 70 MOLECULAR INTERACTIONS OF HEMOGLOBIN

Edited by: D. Labie, C. Poyart, J. Rosa
350 pages/70 French francs/18 US dollars
Functional properties of hemoglobin; Oxidation of hemoglobin; Animal hemoglobins; Abnormal hemoglobins; Post-transcription modifications of hemoglobin.

Vol. 71 CARDIOVASCULAR AND PULMONARY DYNAMICS

Edited by: M. Y. Jaffrin
490 pages/70 French francs/20 US dollars
Flows in large vessels; Measurements in blood vessels; Microcirculation; Cardiac mechanics; Flows in artificial organs; Pulmonary dynamics.

Vol. 72 IMMUNITY IN PARASITIC DISEASES

Edited by: A. Capron, P. H. Lambert, B. Ogilvie, P. Péry
330 pages/70 French francs/18 US dollars
Parasite antigens; Immune mechanisms; Immunological control of parasitic infections.

Vol. 77 PRENATAL ENDOCRINOLOGY AND PARTURITION

Edited by: L. Cédard, C. Sureau
315 pages/60 French francs/18 US dollars
23 articles, 5 in English and 18 in French with English summary Fetal maturity and parturition; Biological survey of human pregnancy; Uterine motricity; Acute fetal distress and labour; Epidemiology.

The third edition of the BDH laboratory wall chart 'Properties of gases' has just been printed.

It measures 620 mm by 890 mm.

It lists over 100 gases.

It gives, where appropriate, the British Standard cylinder colour code, the hazard warning symbols recommended by the Council of Europe, the threshold limit value, the vapour pressure, the specific gravity, the boiling point, the freezing point, the critical temperature, the critical pressure, the formula and the molecular weight of each gas.

It costs £3·25.

Ask for a copy of our leaflet 'Books & Charts' which gives details of all BDH saleable publications.

The Evolutionary Ecology of
Animal Migration

R. Robin Baker

This stimulating and beautifully illustrated book will be an immensely valuable source of reference for biologists with interests ranging from ecology and behavioural studies to conservation and wild-life management. Drawing on a vast and widely scattered literature it has three essential aims: to rationalise the many different interpretations of the term 'migration', to construct and evaluate a model of migration in terms of current evolutionary theory, and to review the great variety of migration patterns shown by animals, both vertebrate and invertebrate. This treatment allows new interpretations to be made of existing information and it will inevitably provoke discussion. The book also presents the first serious attempt to integrate the movement patterns of humans within the general framework of migration.

Hydration of obsidian

T. Laursen & W. A. Lanford

Wright Nuclear Structure Laboratory and Department of Physics, Yale University, New Haven, Connecticut 06520

The hydration of obsidian is studied by measuring hydrogen concentration profiles of natural samples hydrated at 90°C, using the ^{15}N resonance nuclear reaction method. The results of this study are well reproduced by the interdiffusion model of Doremus. The importance of the non-amorphous phase of obsidian is discussed. It is pointed out that the precision methods of measuring hydration profiles now available make it practical to measure hydration rates at room temperature experimentally.

THE study of the reaction between water and obsidian is important to many fields ranging from archaeology, through geochemistry and geophysics, to the technology of radioactive reactor waste consolidation and isolation. Here we investigate the process by which water hydrates a natural obsidian where the hydration is carried out in controlled laboratory conditions. The principal aim is to deal with aspects of the hydration mechanism as it relates to the archaeological technique of dating obsidian artefacts (arrowheads, knife blades, scrapers) based on the extent of hydration on the surface of the object, but the techniques used and conclusions drawn are quite general and should apply to the hydration of many types of glasses.

Understanding the details of the hydration mechanisms is especially important in archaeology to make the best quantitative date assignments based on the hydration[1–3]. Ideally, the archaeologist would like to be able to measure the extent of hydration on a given artefact and to have a method with which to deduce its rate of hydration. With these data he can assign a date. There are now several methods of varying complexity and accuracy for measuring the extent of hydration, and more methods are likely to be developed[4,5]. To be able to deduce the hydration rate, we clearly need to begin with an understanding of the hydration mechanism, and this is the aim of this article. Our general conclusion is that the hydration involves the interdiffusion of hydronium ions (H_3O^+) with mobile alkali ions in the glassy phase of the obsidian. The realisation that natural obsidians can have substantial non-amorphous phases is important for understanding some of the results presented here and elsewhere. Although the aim of the present work is to understand the hydration mechanism, it became clear, from measurements made, that the precision methods now available for measuring hydration profiles make it possible to measure hydration rates directly at room temperature.

Experimental

The obsidian samples used in this study were obtained by fracturing a large piece of 'mahogany' obsidian from the western US. The elemental composition of this obsidian is given in Table 1. The fracturing process produced many thin (few mm) pieces of obsidian with large flat fracture surfaces. This method of surface preparation was chosen both because it duplicates that used to make the archaeological artefacts commonly dated by hydration methods and because our experience with other glasses indicates that other techniques, such as sawing, can affect the apparent hydration rate of the glass. Although no detailed studies are yet available, the sawing may create a network of microcracks which can enhance the initial hydration.

Our experimental procedure is modelled on one developed in a detailed study of the hydration of a commercial soda-lime glass[6]. Our obsidian samples were hydrated for up to 348 h in a bath of temperature-regulated distilled water held at 90°C. The resulting hydration on the surface of the obsidian was profiled quantiatively using the ^{15}N hydrogen profiling method[7]. This uses a narrow isolated resonance in the $^{15}N + {}^1H \rightarrow {}^{12}C + {}^4He + \gamma$-ray reaction as a probe for hydrogen and measures the hydrogen concentration in any solid against depth into that solid. This technique has been previously used to measure hydration profiles in soda-lime glass and is fundamentally similar to that used by Lee *et al.*[8] who were the first to use a nuclear reaction method to profile the surface of hydrated obsidian.

The variable-energy ^{15}N beam from the Yale MP Tandem was used. The experimental arrangement had been calibrated previously, allowing the γ radiation yield curve to be converted to a plot of absolute hydrogen concentration against depth using an energy loss of ^{15}N of 2.0 MeV μm^{-1}. Typical beam intensity was 2×10^{-9} A with a beam spot of 10 mm^2. We were concerned that the ^{15}N beam might disturb the hydrogen distribution during the analysis and to check this, some of our measurements were repeated after completing the profile. These repeat measurements showed no change in the hydrogen distribution. Detailed description of the experimental system and a comparison between this method and other analytical techniques for measuring hydrogen profiles are given elsewhere[7,4].

Results

The measured hydrogen profiles for our hydrated obsidians are summarised in Figs 1 and 2. Because the rate of hydration is expected to be limited by diffusion, we assumed that the thickness of the hydration profile would increase proportionally to the square root of the hydration time. This is shown in Fig 1 where the measured depth into the sample at which the hydrogen concentration has decreased to half the value near the surface is plotted against the square root of the hydration time: the expected $t^{1/2}$ dependence is obtained.

Clearly, the hydration is proportional to $t^{1/2}$, and so to discuss the shape of the hydration profile, it is convenient to combine all the data by removing this explicit time dependence—that is, to plot hydrogen concentration against depth divided by the square root of the hydration time ($x/t^{1/2}$). This is shown in Fig 2. The typical error bars shown on a few of the points reflect only statistical uncertainties in the data. By thus combining all these data, the statistical uncertainty associated with individual data points as well as any local variations in the composition of the

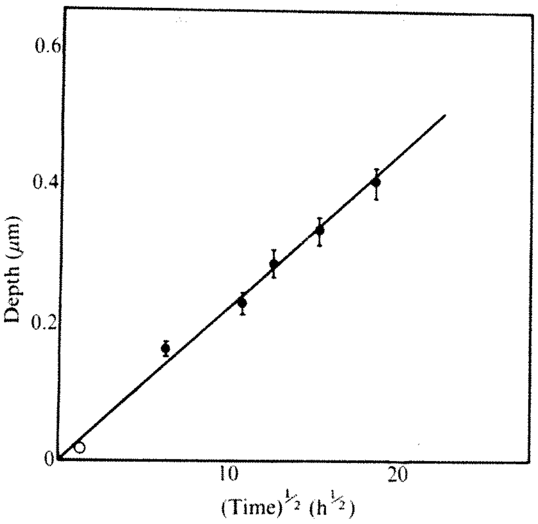

Fig. 1 The penetration depth as function of the square root of the hydration time. The penetration depth is defined as the depth to half-maximum hydrogen concentration. The error bars reflect the statistical uncertainties only. The open circle shows the penetration in an unhydrated sample exposed to air at room temperature for two months. The hydration time has been converted to the equivalent time at 90 °C by an extrapolation according to the Arrhenius equation assuming an activation energy of 20 kcal mol^{-1}.

obsidian become less important as we consider only the average profile.

The hydration profile shown in Fig. 2 has the shape expected from other experimental measurements[8,5] and for the Doremus interdiffusion model for the hydration of glasses[9]. In fact, the solid lines in Figs 1 and 2 result from a calculation based on this model. It is reassuring that the hydrogen content of the unhydrated obsidian (0.3×10^{21}H atoms cm^{-3}) deduced from the ^{15}N profile measurements agrees with the results of the commercial analysis of the obsidian's composition as given in Table 1.

Hydration mechanism

There has long been interest in the mechanism for the hydration of alkali glasses—such as obsidian—and there are several hypotheses on the important hydration mechanisms. We will compare our results with the Doremus model[9], in which the hydration is the result of ionic interdiffusion between the alkali ions in the glass with hydronium ions formed at the surface. Doremus compared the shape of the hydration profile predicted by his model with that measured by Lee *et al.*[8] on the surface of an archaeological artefact. Our more complete results presented here agree entirely with this first single comparison.

A second hydration mechanism which has been commonly mentioned is that of diffusion of molecular water into the glass matrix. We are not aware of reliable experimental evidence favouring this above the ionic interdiffusion model (although molecular water may diffuse into the ion-exchanged hydrated glass). One strong piece of evidence favouring the interdiffusion model is the depletion of alkali ions observed in hydrated glasses, including obsidians. This is observed both in leaching experiments where the amount of ions which diffuse out of the glass is measured, and in direct measurements of the profiles of the alkali elements in the hydrated glass[5,6]. A second general piece of evidence favouring the interdiffusion model is that the glasses which hydrate are ionic conductors whereas glasses without mobile ions do not generally hydrate (such as SiO_2).

The Doremus model[9] is based on the fact that in a glass such as obsidian, the only mobile charge carriers are monovalent alkali ions such as Na^+ and K^+. These positive ions are very mobile and would diffuse out of the glass were it not for the electrostatic attraction between them and the immobile anions in the glass. However, if some other positive ion such as hydronium (H_3O^+) is available to substitute for these alkali ions, the mobile alkali ions and the hydronium ions can interdiffuse, resulting in hydration of the glass. Hydronium ions are available from water on the surface of the glass reacting with Na in the glass: $2H_2O+Na^+ \text{(glass)} \rightarrow H_3O^+ \text{(glass)} + NaOH$ and through a similar reaction with K^+. We discuss H_3O^+ rather than H^+ or some other ion because results with other glasses indicate that about three hydrogen atoms replace every alkali atom during hydration[6]. The interdiffusion model is convenient because it can be transformed to an equivalent simple diffusion problem with a concentration-dependent diffusion coefficient $\tilde{D} = D_H D_A/(C_H D_H + C_A D_A)$ for which standard methods of solution exist where D_H and D_A are the diffusion coefficients of hydronium and the alkali ion, and C_H and C_A are their respective concentrations. Hence if one has a glass with a mobile alkali ion (such as Na^+) interdiffusing with hydronium, one can immediately predict the shape of the hydration profile and the rate of hydration given values of the diffusion coefficients of the Na^+ and H_3O^+. In the results presented here, the interdiffusion problem was solved numerically. In principle, when considering the profile shape one also has to consider the etching of the surface of the hydrated obsidian. However, the fact that the data fall in a straight line in Fig. 1 and that obsidians are known to hydrate to thicknesses of many microns implies the etching is very slow, so we have ignored it.

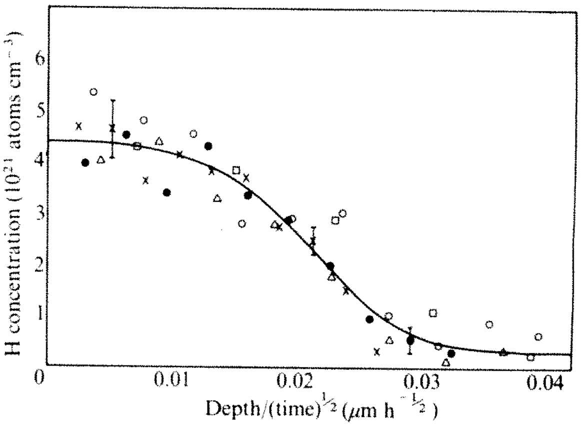

Fig. 2 The measured hydrogen profiles of the hydrated samples are here shown by using a reduced depth scale, which is the actual depth divided by the square root of the hydration time. The solid curve is the prediction of the interdiffusion model with $D_H = 1.4\times10^{-16}$ cm^2 s^{-1} and $D_A = 1.4\times10^{-14}$ cm^2 s^{-1}. The calculated profile has been normalised to the data in terms of the amount of hydrogen in the fully hydrated glass at the surface (see text). □, 40 h; △, 116 h; ○, 158 h; ●, 234 h; ×, 348 h.

In the present case, the glass contains both Na^+ and K^+ (see Table I), and both ions are expected to interdiffuse with hydronium. However, it turns out that as long as $D_A \gg D_H$ the hydrogen profile predicted by the interdiffusion model is not very sensitive to the precise value of the diffusion coefficient for the alkali ion (D_A). Increasing D_A by several orders of magnitude has only a small effect on the shape of the hydrogen profile and the rate of hydration. The underlying reason for this insensitivity to D_A is that as long as $D_A \gg D_H$ the rate-controlling step in the hydration process is the diffusion of hydronium into the glass.

Hence in a glass, such as the obsidian considered here, one expects the total measured hydrogen profile to represent the sum of two components (one for K and one for Na), but, as both profiles are similar, the sum will not be easily distinguished experimentally from that resulting from a single ion. Hence for simplicity we consider model calculations with only a single alkali ion, but the solution may be interpreted as the sum of two.

Figure 2 (solid line) shows the prediction of the interdiffusion model with $D_A = 1.4\times10^{-14}$ cm^2 s^{-1} and $D_H = 1.4\times10^{-16}$ cm^2

s^{-1}. As is evident, this prediction is in excellent agreement with the data. The shape of the predicted profile depends only on the ratio D_A/D_H, whereas the rate (shown in Fig. 1) is only weakly dependent on the ratio and proportional to D_H.

Because there are no measurements of D_A and D_H available, they were treated as free parameters to obtain the agreement between model predictions for the rate of hydration (Fig. 1) and the shape of the profile (Fig. 2). The diffusion coefficient for hydronium, thus obtained, is similar to that needed to understand the hydration of soda-lime glass and is consistent with other reported measurements[6]. The corresponding diffusion coefficient for the alkali ion is one order of magnitude smaller than that needed to understand the hydration of soda-lime glass[6]. However, the present obsidian has much less alkali than the soda-lime glass, which has 15.9% Na_2O, and the D_{Na} decreases rapidly with the concentration of Na^+ ions in the glass. Also, some of the alkali ions are K^+, which are less mobile than the Na^+, and hence D_A should be somewhat smaller than D_{Na}. Extrapolating the data for soda-lime glass[11] indicates that qualitatively we should expect D_A to be an order of magnitude smaller in this obsidian than in the soda-lime glass of ref. 6, which again agrees with our experimental results. There are also measurements of D_{Na} in obsidian in the temperature range 350–850 °C. Extrapolating these results to the 90 °C of the present hydration implies D_{Na} to be of the order of 5×10^{-14} with an uncertainty resulting from the extrapolation of at least an order of magnitude. Hence we see that the interdiffusion model predicts both the shape and absolute hydration rate with values of D_A and D_H (the only parameters in the theory) consistent with the available measurements of these diffusion coefficients.

One point, not discussed above, is important for reconciling the measurements reported here and their interpretation within the interdiffusion model with the results of others. The hydrogen profile shown in Fig. 2 has been arbitrarily normalised to the data in terms of the amount of hydrogen in the fully hydrated glass at the surface. If the hydrogen-bearing ion which replaces the alkali ions in the glass is hydronium, and if all the alkali ions are allowed to participate in the interdiffusion, then we expect the hydrogen content of the hydrated glass to correspond to a 3-atom hydrogen replacement for each alkali ion, as has been observed in manmade glasses (W.A.L. *et al.* unpublished and ref. 6). The results shown in Fig. 2 indicate only about half this amount of hydrogen. Measurements of the profiles of the alkali ion concentration in hydrated obsidian[5] also indicate that only about half of these ions are removed during the hydration, in contrast to the results in soda-lime glass where the sodium is completely removed.

The reason the alkali ions are only partially depleted in hydrated obsidian is not completely clear. One possibility is that some of the alkali ions are immobilised and, hence, cannot take part in the ion exchange. This immobilisation may result because in addition to the glassy phase, obsidians typically contain large amounts of crystal inclusions. A recent survey by Ericson *et al.* using optical methods indicated that ~10% of obsidians were crystal inclusions[13]. In addition to the crystal inclusions which can be seen microscopically, X-ray studies of purely 'glassy' obsidian show weakly developed lines which correspond to the minerals to which the obsidian would have crystallised had it cooled more slowly[14]. These X-ray studies indicate that obsidians can have small structures which, although not optically visible, may behave more like crystal inclusions than amorphous glass.

A second possibility is that the two alkali ions present (Na^+ and K^+) may interact immobilising some of the ions. This may be related to the dramatic decrease in ionic conductivity observed in mixed alkali glasses over those made with only one alkali element[10].

Table I Chemical analysis of obsidian

Chemical component	Weight %
SiO_2	75.85
Al_2O_3	12.81
Fe_2O_3	0.85
FeO	0.57
MnO	0.05
TiO_2	0.25
CaO	0.48
MgO	0.16
Na_2O	3.74
K_2O	4.20
H_2O^+	0.15
H_2O^-	0.008
P_2O_5	0.03
CO_2	0.05
Total	99.148

The analysis was carried out by York Research Corporation, Stamford, Connecticut, using atomic absorption spectroscopy and other methods.

The presence of a crystal component in obsidian has several implications. The crystal material is expected, if it hydrates at all, to hydrate many orders of magnitude more slowly than the glass. Feldspars contain proportionally much more of the Na and K than the bulk composition and, consequently, their existence substantially depletes the alkali component of the glass phase. A 10% component of potassium or sodium feldspar incorporates ~20% of the total alkali. In the present case, it is difficult to estimate quantitatively how much of the sodium and potassium given in the bulk composition (Table I) exists in the glassy phase and should then exchange with hydrogen in the hydration process: if 10% of the obsidian is crystallised in potassium or sodium feldspars[13] and if roughly an equal amount of alkali is immobilised in embryonic crystals, then the observed hydrogen content is consistent with each alkali ion being replaced with one H_3O^+ ion.

The suggestion that a fraction of the alkali ions in obsidian is immobilised is consistent not only with this interpretation of our present data but also with the recently reported[5] partial depletion of alkali ions in hydrated obsidian. It also provides a natural explanation for the fact that no correlation was found between alkali content and hydration rate for a variety of obsidians[1], whereas it is well known that for synthetic glasses the alkali content is key to the hydration[10]. If an unknown fraction of the alkali is immobilised in crystalline structures, the bulk alkali content may not reflect the true alkali content in the glass phase of the obsidian. On the other hand, the interdiffusion model predicts an increase in hydration rate with alkali content because of the known increase in alkali diffusion rate with increased alkali content. This should also be realised as a correlation between the maximum hydrogen content in fully hydrated obsidian with hydration rate. Such a correlation has already been reported in the hydrogen profile measurements of Lee *et al.*[8] The importance of the non-amorphous phase of obsidian in explaining the lack of correlations between bulk composition and density has already been reported[13].

Direct measurement of hydration rate at room temperature

The ^{15}N hydrogen profiling method can quantitatively measure hydrogen profiles as thin as a few hundred Angstroms. If the thickness of the hydrated surface layer (X) varies with time as $X^2 = KT$, archaeological evidence shows K varies from <1 to 20 μm^2 per 1,000 yr (ref. 2). Assuming, for example, $K = 10\ \mu m^2$ per 1,000 yr means that, if a piece of obsidian is fractured and the resulting fresh fracture surface is exposed to the ambient environment for one year, the resulting hydration layer will be 1,000 Å thick. This is easily measurable by the ^{15}N hydrogen profiling method. By such a procedure, it should be possible to determine the hydration rate for individual artefacts.

For example, the open data point in Fig. 1 is the hydration thickness (200 Å) of a sample of obsidian which was not exposed to the 90 °C water bath but which, instead, was in an air environment for two months before being profiled. The hydration rate deduced corresponds to $K = 2.4\ \mu\text{m}^2$ per 1,000 yr, which agrees with that predicted from the archaeological results.

A practical use of such measurements might be to fracture the artefact to be dated and return it to the environment in which is was found for one year; by measuring the hydration profile on the 'one-year-old' surface, a hydration rate is determined which is automatically averaged over annual temperature variations. By then measuring the hydration profile on an original surface, the age of the artefact could be deduced.

Conclusion

We see that the interdiffusion model predicts the shape of the hydration profile and the rate of hydration in good agreement with our data. The values of the two free parameters in this model (D_A and D_H) which are needed for agreement are, as well as can be presently determined, consistent with other measurements. Finally, we emphasise that the experimental methods described here can be useful in characterising the hydration rates of other glasses, whether the glass is a single archaeological artefact[2,15], a scientific or commercial glass, or a glass designed to isolate radioactive reactor wastes.

Oceanic plate motions driven by lithospheric thickening and subducted slabs

Bradford H. Hager

Department of Geological Sciences, Harvard University, Cambridge, Massachusetts 02138

The thickening of the cooling oceanic lithosphere results in a significant driving force that is distributed over the area of the plates. Simple flow models show that this force may be more important in driving oceanic plates than that force from sinking lithospheric slabs at subduction zones.

IN the past decade, the theory of plate tectonics has been quite successful in explaining many geological and geophysical observations. Nevertheless, plate tectonics remains primarily a kinematic theory. Although some form of thermal convection must be responsible for the plate motions[1], the details of the driving mechanism and flow in the mantle accompanying the plate motions are still uncertain. The lithosphere, the mechanically strong thermal boundary layer which makes up the plates, probably has an important influence on mantle flow: the largest temperature gradients in the Earth occur across the lithosphere. As convection is driven by the body forces caused by differences in temperature, the plates might be expected to play an important part in governing convection in the Earth. Thus, to understand the dynamics of mantle convection, it is important to isolate and understand the effects resulting from the plates themselves.

Because the plates are denser than the mantle below, they are gravitationally unstable and ultimately sink into the mantle at subduction zones. The sinking of the dense subducted slabs into the mantle provides a potentially important driving mechanism for plate motions which has been considered in several investigations of the forces driving the plates[1–4].

Important density contrasts are not, however, limited to the sinking slabs. As the oceanic lithosphere moves away from the ridge where it is created, it becomes thicker because cooling penetrates deeper into the mantle. This thickening of the dense lithosphere leads to horizontal density differences across distances of the order of the plate dimensions. Simple flow models presented here show that these density contrasts are sufficient to drive plate motions at rates of centimetres per year. In fact, the body forces from the thickening of the lithosphere seem to be even more important in driving plates than the body forces associated with the subducted slabs.

Model of the lithosphere

The thermal evolution of the oceanic lithosphere is fairly well understood. Many of the properties of the oceanic lithosphere can be explained by simple models based on cooling the mantle from above[1,5–8]. The essential features of these models are illustrated by a model of a cooling halfspace[6,7]. In this model, shown in Fig. 1, mantle material at temperature T_0 rises in the vicinity of an oceanic ridge and moves horizontally away from the ridge at a velocity u which is constant and independent of depth. At distances not too close to the ridge, the temperature at depth ζ is given in terms of an error function:

$$T(z) = T_0 \operatorname{erf}\left(\zeta/2(\kappa t)^{1/2}\right) = T_0 \operatorname{erf}\left(\zeta/2(\kappa x/u)^{1/2}\right)$$

where κ is the thermal diffusivity, t is the time since the material was at the ridge, and x is the horizontal distance from the ridge. The second equality results from the relationship between time and distance from the ridge, assuming constant spreading velocity u.

If the base of the thermal boundary layer constituting the lithosphere is defined by some critical temperature T_l, the thickness of the lithosphere d is given by

$$d = 2(\kappa x/u)^{1/2} \operatorname{erf}^{-1}(T_l/T_0)$$

It is a property of the error function solution that the average temperature, and therefore the average density, of the lithosphere is independent of distance from the ridge. Thus the lithosphere can be thought of as a cool, dense, mechanically strong layer of constant mean density which grows thicker away from the ridge as the material formerly below the lithosphere cools and becomes part of it.

As the dense lithosphere thickens by accretion, it subsides into the less dense mantle beneath, resulting in an increase in ocean depth away from the spreading ridge. This sinking is

0028–0836/78/0276—0156$01.00

inferred to lead to an essentially complete isostatic compensation of the thickening lithosphere because the free air gravity anomalies observed over oceanic ridges and basins are small[9]. Isostasy requires that the elevation of the seafloor, η_t, and the elevation of the base of the lithosphere, η_b, both referred to their final depths just before subduction, are related by

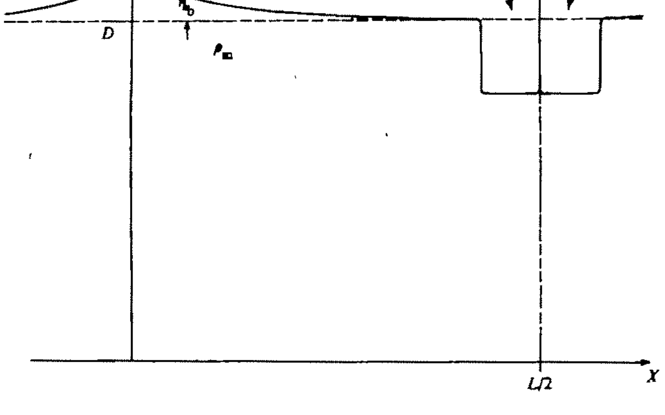
$$\eta_b = ((\rho_l - \rho_w)/(\rho_l - \rho_m))\eta_t$$

where ρ_l, ρ_w, and ρ_m are the densities of the lithosphere, seawater, and the mantle, respectively. The boundary layer theory predicts that the increase in depth of the ocean owing to the isostatically compensated thermal contraction of the surface layer should depend on the square root of age or distance from the ridge crest, in accord with observation to plate ages of at least 80 Myr (ref. 8).

Eventually, the dense plate plunges into the mantle at a subduction zone. As it sinks it may pull the rest of the plate with it, as suggested by Elsasser[10]. Simple dynamic models of mantle flow[4] and phenomenological studies of forces on plates[2,3] have indicated that the body forces of the sinking slab may provide an important part of the forces driving the plates, although detailed models involving the transmission of the force from the sinking slab to the horizontal plate have not yet been analysed.

The thickening of the lithosphere itself is another source of density contrast that can cause flow and plate motion. Figure 1 shows that the dense lithosphere is separated from the less dense mantle below by a sloping interface. The situation is analogous to a dense fluid overlying a less dense fluid in a tank. Clearly, if the interface between the two fluids slopes, the configuration is not in equilibrium, and the dense fluid will begin to sink at its thick end while the less dense fluid will rise at the other end where the dense layer is thinnest. Similarly, the thick lithosphere far from the ridge will sink, and the less dense mantle will rise under the ridge. There will be an accompanying surface flow from ridge to trench, corresponding to plate motion, with a return flow at depth to complete the mass circuit. As the mantle material rises continuously under the ridge, it cools and accretes onto the dense lithosphere. The lithosphere is reheated and resorbed as it sinks into the mantle; this would cause steady state thermal convection driven by body forces associated with the thickening of the lithosphere at the surface if accretion and resorption occurred at the appropriate rate.

Fig. 1 Schematic representation of the geometry assumed in the flow models. The elevation of the sea floor, η_t, and the elevation of the base of the lithosphere, η_b, are related because the lithosphere is in isostatic equilibrium. Because the density of the mantle, ρ_m, is less than the density of the lithosphere, ρ_l, horizontal density contrasts due to the thickening lithosphere and subducted slab drive the plate towards the trench. The core-mantle boundary is at $z = 0$.



The velocity of this plate-driven flow depends on the extent of the horizontal density differences. If the top and bottom of the lithosphere were flat, there would be no horizontal density differences, so there would be no motion. One measure of the magnitude of the driving force is the horizontal mass difference, the volume integral of the horizontal density contrast. If isostatic compensation is assumed, the horizontal mass difference accompanying the change in depth of the base of the lithosphere is equal in magnitude to the horizontal mass difference accompanying the change in elevation of the sea floor. The total horizontal mass difference is 9.2×10^{12} kg m^{-1} for a ridge whose elevation decreases as the square root of the distance, from 3 km at the ridge crest to 0 km, 6,000 km away assuming a density difference of 2.3 Mg m^{-3} between the lithosphere and seawater.

The total horizontal mass difference inherent in the subducted slab is not as well constrained as that resulting from the thickening of the cooling plate because the thermal evolution of a subducted slab depends on complicating factors such as viscous dissipation, phase changes, and the variation of the ambient temperature of the mantle with depth[11]. In a model of the evolution of a 120-km thick slab calculated by Schubert *et al.*[12], including the effects of frictional heating and phase transitions, the horizontal mass difference is 4.5×10^{12} kg m^{-1}, about a third of which results from elevation of the phase boundary between the olivine and spinel phases at a depth of 350 km. This model predicts a much larger horizontal mass difference than other slab models[1,11] but this mass difference is still a factor of 2 smaller than that calculated for the thickening of the cooling surface plate. Thus the body force associated with the cooling plate may be more important in driving plate motions and mantle flow than the body forces associated with the sinking slabs. Of course, the flow in the mantle owing to a distribution of body forces depends on the position as well as the magnitude of the body forces, so it is necessary to compute flow models before evaluating the relative importance of these two body forces resulting from the thermal evolution of the lithosphere.

Viscous flow models

To facilitate comparison of the relative magnitudes of the two driving mechanisms, the flow driven by the thickening lithosphere alone is computed for comparison with the flow driven solely by the sinking slab. The rheology of the mantle is taken as newtonian viscous and the fluid is incompressible, which is consistent with the commonly used Boussinesq approximation Neither assumption is strictly justified for flow in the Earth, but this is not expected to invalidate the qualitative conclusions to be drawn from the models. Plate geometries and the distribution of body forces are assumed to be in steady state, so there is no time dependence in the models; streamlines and particle paths coincide.

The Stokes equations for a fluid in a two-dimensional Cartesian frame are solved by decomposing horizontal variations of the flow variables into Fourier series and solving for their depth dependences for each term in the series Where volumetric density variations exist, they are expressed as equivalent surface density distributions on planes spaced closely enough that the computed flow pattern is not affected appreciably by this approximation.

The shear stress is zero at the top and bottom of the model, which correspond to the ocean floor and core-mantle boundary. According to standard practice[6,19], no vertical displacement of these boundaries is permitted. The vertical displacement which would result if a boundary were permitted to deform is, to first order, the topography which could be supported by the normal stress at the undeformed boundary. As this topography is negligible compared to the depth of the model, the flow geometry is not appreciably affected by this approximation. The boundary conditions at the sides are also free slip, equivalent to the periodic array of plates shown in Fig. 1. The width of each cell is 5,570 km. The models shown below have a viscosity of 10^{21} N s m^{-2} throughout, the average mantle viscosity determined in studies of postglacial rebound[13].

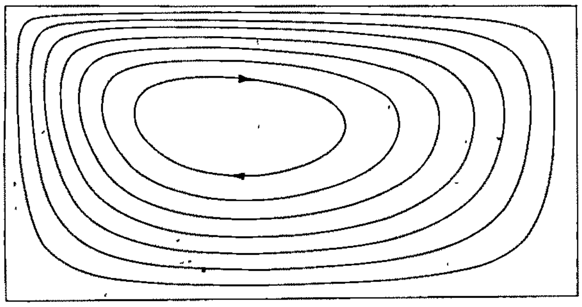


Fig. 2 Streamlines for flow driven only by the thickening lithosphere. The maximum magnitude of the stream function is 8.2×10^7 cm^2 yr^{-1} and the contours are equally spaced. The average surface velocity is 1 cm yr^{-1}. The maximum velocity is 1.6 cm yr^{-1} and occurs at the surface. The viscosity is 10^{21} N s m^{-2} throughout.

The streamlines for flow driven by the thickening lithosphere are shown in Fig. 2. The horizontal density contrast from the thickening of the plate is included at a depth of 64 km. The density contrast is that needed to compensate for a seafloor elevation decreasing as the square root of the distance from the ridge from a maximum elevation of 3.0 km, the topography appropriate for a spreading rate of 7 cm yr^{-1}. A density contrast between the lithosphere and seawater of 2.3 Mg m^{-3} is assumed.

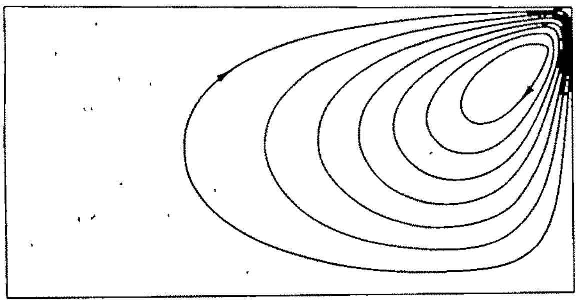
The average velocity at the surface is 1 cm yr^{-1}. Near the surface, the streamlines are essentially parallel, indicating that the flow driven by the thickening lithosphere causes little deformation of the surface. Calculated shear stresses are of the order of 0.5 MPa.

Details of the flow depend on the viscosity structure. Increasing the viscosity in the lithospheric layer by a factor of 10 decreases the average surface velocity by a factor of 2. The average surface velocity increases to 16 cm yr^{-1} if a 64-km thick low viscosity channel of 10^{18} N s m^{-2}, similar to that proposed to lie under oceans by Artyushkov[14], is included at the base of the lithosphere. One could easily match the surface velocity of 7 cm yr^{-1} with the density distribution driving the flow in this model by a suitable selection of parameters and hence the model of the plate-driven flow can be made entirely self-consistent.

The streamlines for flow driven by the sinking of a subducted slab are shown in Fig. 3. The density contrast in the slab decreases linearly with depth from 0.06 Mg m^{-3} at the surface to zero at a depth of 670 km. This decrease in density with depth, which might result from heating the slab as it sinks, was chosen so that the calculated stresses would roughly match the seismic observation that slabs are in down-dip compression below a depth of 300 km (ref. 15).

The average velocity at the surface is 1 cm yr^{-1}, although the velocity reaches 8 cm yr^{-1} in the region of the sinking slab, where the flow is concentrated. The converging streamlines along the surface indicate that the near-surface layers experience extensional stress.

Fig. 3 Streamlines for flow driven by a sinking slab. The density contrast in the slab varies linearly from 0.06 Mg m^{-3} at the surface to 0 Mg m^{-3} at a depth of 670 km. The maximum amplitude of the stream function is 14.8×10^7 cm^2 yr^{-1} and the contours are equally spaced. The average surface velocity is 1 cm yr^{-1}, although vertical velocities in the subducted slab reach 8 cm yr^{-1}. The viscosity is 10^{21} N s m^{-2} throughout.



As before, varying the viscosity structure changes the flow somewhat. Increasing the viscosity of the lithosphere by an order of magnitude decreases the average surface velocity by a factor of 2. Alternatively, including the 64 km thick low viscosity channel of 10^{18} Ns m^{-2} leads to an average surface velocity of 6 cm yr^{-1}, compared with 16 cm yr^{-1} for the same viscosity distribution with the flow driven by the thickening lithosphere.

Discussion

For the constant viscosity models, the average surface flow driven by the thickening lithosphere is as large as that driven by the sinking slab. A low viscosity channel increases the surface flow for the thickening lithosphere model more than for the slab model. Also, the 670-km slab in the model is longer than the seismicly determined length of most subducted slabs[15]. Therefore, on a worldwide basis, the surface flow driven by the thickening oceanic plates might well be larger than the surface flow driven by subducted slabs.

For viscous flow driven by body forces, the scale of the flow depends on the distribution of those forces. The density differences associated with thickening oceanic plates are spread out over distances equal to the dimensions of the plates, while the body forces associated with subducted slabs are more localised. The flow driven by the sinking slabs is concentrated in the region of subduction, where it may be important in the local deformation associated with bending and underthrusting of the lithosphere. In contrast, the flow driven by plate thickening is more global in scale, in accord with plate motions that are coherent over large distances.

The predicted dependence of ocean depth on the square root of age is not valid beyond about 80 Myr, which corresponds to lithospheric thickness on the order of 130 km, after which the thickness may not increase appreciably[8]. Consequently the driving force from the thickening lithosphere is distributed primarily over that part of a plate which is <80 Myr old. For very slowly spreading plates, this force can probably be approximated as a boundary force acting on the ridge itself[1-4,14,16]. Nevertheless, as Hales[17] and Lister[18] have pointed out, for spreading rates typical of oceanic plates, this driving force will be distributed over substantial areas of the plates.

The distinction between an edge force and a distributed force has important dynamic implications. The velocities of oceanic plates are observed to be relatively independent of area; the small Cocos Plate, the intermediate Nazca Plate, and the large Pacific Plate all move at about the same rate[2]. For plates spreading at equal rates, the driving force from the thickening lithosphere is greater for large plates than for small ones. Also, the body force in the subducted slab, which must depend to a large extent on the time a plate cooled at the surface before subducting, should be greater for a large, old plate than for a small, young one. For the plate velocities to be relatively independent of area, there must be a resisting force which increases as the area of a plate increases. Drag at the base of the lithosphere is likely to satisfy this criterion.

For drag at the base of the lithosphere to be an important resisting force, oceanic plates, on average, must be moving faster than the underlying mantle. Richter showed that the shear generated by a moving lithosphere should exert a strong organising influence on the flow in the mantle, resulting in a coherent large scale convection pattern dominated by the plate motions[19].

The nature of the force resulting from the thickening of the oceanic lithosphere suggests that oceanic plate velocities might be self-limiting. The slope at the base of the lithosphere is greater for slowly moving plates than for rapidly moving ones. Therefore, the driving force from the thickening of the plates is larger for slowly moving plates, all other factors being equal. If a plate were to move away from a ridge more rapidly, the ridge topography and accompanying topography at the base of the lithosphere would become flatter, providing less drive. Oceanic plates might all move at about the same speed[2] because their associated ridges are spreading at terminal velocity, rather than because their slabs are sinking at terminal velocity[2–4], as old slabs might be expected to have a larger terminal velocity than young ones.

Conclusions

The density contrast at the Earth's surface associated with the cooling and thickening of the oceanic lithosphere provides a significant driving force for plate motions. Simple numerical models of mantle flow show that this plate-driven flow may be more important in generating coherent surface motions than the sinking slab, although flow driven by the sinking slab is likely to be important locally in the region of subduction. Although these models do not consider how oceanic plate motions originate, they do show that the horizontal density differences resulting from the cooling of these plates are capable of sustaining this motion.

The driving force on a plate from the thickening oceanic lithosphere is distributed over the area of the plate. As oceanic plate velocities do not depend on plate area, there is likely to be a significant resisting drag proportional to area at the base of the lithosphere. Thus the plate motions should be important in determining the large scale flow in the mantle.

The magnitude of the plate-driven flow depends on the slope of the boundary between the dense lithosphere and the underlying mantle. As this slope decreases as spreading rate increases, plate-driven flow may be self-limiting, helping to account for the observation that oceanic plate velocities show little variation.

I thank R. J. O'Connell, G. F. Carrier and R. A. Verrall for helpful discussions. This study was supported by a NSF Graduate Fellowship.

Colicin K acts by forming voltage-dependent channels in phospholipid bilayer membranes

Stanley J. Schein

The bactericidal action of colicins K, E1, Ia, and other functionally related colicins involves disruption of active transport and leakage of ions from the cell. We show that a single colicin K molecule can form a voltage-dependent, relatively nonselective, ion-permeable channel of a few picosiemens conductance in a planar phospholipid bilayer membrane. In a membrane containing many of these channels, the ratio of the number of conducting to nonconducting channels changes e-fold per 3.7 mV. We suggest that the physiological effects of colicin K and functionally related colicins result from their ability to form ion-permeable channels in the bacterial plasma membrane.

COLICINS, bactericidal proteins (MW 50,000–100,000) produced by *Escherichia coli*, are of three major functional types: E1, E2 and E3. (For reviews of the physiology of colicin action see refs 1 and 2.) The cellular targets of action of types E2 and E3 are DNA and ribosomal RNA, respectively. The precise target and mechanism of action of the E1 type are not known, but these colicins are thought to act by making ion-permeable channels in the bacterial plasma membrane because: (1) they discharge the 'energised state' of the plasma membrane[1–7] without inhibiting respiration[1,8,9] or inducing measurable proton flux[6,7,10,11], and (2), an early effect of their action is net efflux of potassium from the bacterium[10,12–17]. (As macroscopic electroneutrality requires that net potassium efflux be accompanied by either efflux of anions and/or influx of other cations, the colicin-induced permeability is apparently rather nonselective.) Channel formation by these colicins is also consistent with observed single hit killing[18–20], and a *p*H or voltage dependence of the induced channels would explain the protective action of uncouplers of oxidative phosphorylation (such as FCCP) and of other treatments that discharge the energised state of the plasma membrane[16,18,21].

We report here that colicins K, E1, and Ia (members of the E1 functional type) form voltage-dependent, relatively nonselective ion-permeable channels in planar phospholipid bilayer membranes. We believe that this is their primary action on cells and accounts for the observations cited above. We present here data obtained from colicin K; closely related effects are obtained with E1 and Ia.

Conductance is a function of voltage

Planar phospholipid bilayer membranes (area $\approx 0.01\ \text{mm}^2$) separating two salt solutions were formed at room temperature by the union of two monolayers[22] of crude soybean phospholipid (lecithin type II from Sigma)[23] from which neutral lipid was removed[24]. After addition of colicin K to the front (or *cis*) compartment to a concentration of from 0.2 to $200\ \text{ng ml}^{-1}$, known voltages were applied across the membrane, and the resulting current responses were measured[25]. The conductance (g) of the membrane in symmetric salt solutions is defined as current divided by voltage ($g = I/V$), where V is the potential of the rear (or *trans*) compartment; in the absence of colicin, g is about 10 pS.

Figure 1 shows the typical response of a membrane which separates symmetric salt solutions and has been treated with

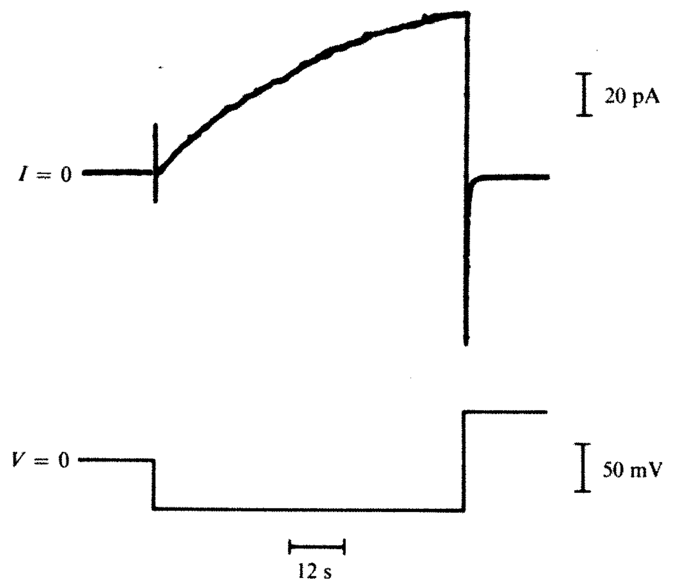

Fig. 1 Current response of colicin K-treated membrane to voltage. After formation of the membrane (in 100 mM KCl + 5 mM $CaCl_2$ + 1 μM EDTA + 5 mM 2[*N*-morpholino]ethane sulphonic acid, all adjusted to *p*H 6.1 with KOH), colicin K produced by *E. coli* was added to the front (or *cis*) compartment to a concentration of 100 ng ml^{-1}, and the record was obtained about 10 min later. The *cis* compartment was connected to virtual ground; *V* is the potential of the rear (or *trans*) compartment, analogous to the inside of the target bacterium. At the 'blip', a voltage of −50 mV was applied across the membrane. The current rises with approximately $1-\exp(-t/\tau)$ kinetics ($\tau \approx 25$ s) to a steady-state value of 80 pA, which corresponds to a conductance of 1,600 pS. At this point the potential was reversed to +50 mV. The instantaneous current is of the same magnitude but opposite sign as that at −50 mV, and decays rapidly to a very low value. The steady-state colicin-induced conductance at −50 mV is 400 times that observed at +50 mV. Stock solutions of colicin (~1 mg ml^{-1}) in 500 mM KCl + 50 mM potassium phosphate (*p*H 6.0) or in 300 mM NaCl + 50 mM Tris (*p*H 7.4) were stored in small vials at −70 °C. For a given day's experiments, the contents of a vial were thawed and, along with subsequent dilutions, stored on ice. Colicin K handled in this way was indefinitely stable (>6 months) with respect to its action on lipid bilayers; when left at room temperature for a day or two, however, it lost virtually all of its activity on bilayers.

colicin K on one side. When a negative voltage of sufficient magnitude (in this case −50 mv) is applied, current (and therefore conductance) rises with approximately $[1-\exp(t/\tau)]$ kinetics, with τ in this case about 25 s and the steady-state conductance about 1,600 pS. If the sign of the voltage is reversed after this rise, the current initially has the same magnitude (but, of course, the opposite sign), and then decays rapidly within a second to a low value little greater than that for an unmodified membrane. The steady-state conductance is extraordinarily voltage dependent (Fig. 2). Conductance is maximal at large negative membrane potentials and is virtually zero at potentials > -10 mv (Fig. 2*a*). τ Is also voltage dependent, decreasing as $|V-V_0|$ increases. (See below for definition of V_0.) Over long periods ($t \gg \tau$), there is a slow linear rise in the magnitude of the voltage-dependent conductance.

Single channel behaviour

The colicin-induced conductance described above is due to ion-permeable channels. At small colicin concentrations, discrete current 'jumps' are seen at constant voltage (Fig. 3). The conductances corresponding to these jumps are fairly uniform and, in 100 mM KCl, are about 1.5–3 pS for colicin K produced by *E. coli*. For colicin K produced by *Proteus mirabilis*, the jumps are about 10 pS; this surprising difference is discussed below. These unit conductance jumps are much too large for a shuttling ion carrier, and must therefore result from ion-permeable channels[26,27]; they are comparable in size to those of the sodium and potassium channels in nerve and the cholinergic channels at the neuromuscular junction[28]. The linear dependence of maximal steady-state conductance on colicin concentration (Fig. 4) implies that each voltage-dependent channel is formed by a single colicin K molecule.

The macroscopic voltage dependence (Fig. 2) is reflected in single channel behaviour (Fig. 3); that is, channels are almost always on at large negative voltages and almost always off at small negative or positive voltages. The data in Fig. 2*a* are replotted in Fig. 2*b* according to the Boltzmann relationship[25]. Over a wide voltage range the ratio of the number of open to closed channels changes *e*-fold per 3.7 mV. The potential at which half the channels are open (ratio = 1) defines the 'switching voltage' (V_0) of the channel, in this case −31 mV.

Similar results were obtained in membranes formed from whole *E. coli* phospholipids or from mixtures of purified bacterial phospholipids mimicking that composition. The number of channels obtained for a given concentration of colicin was 1–10% of the number obtained with membranes formed from crude soybean phospholipids.

Ion selectivity

Colicin K-induced channels are cation selective, but poorly so. A ratio of 10:1 for NaCl concentrations across the membrane (50 mM:500 mM) produces a diffusion potential of 33 mV (dilute NaCl side positive). This was established by determining the reversal potential either for the macroscopic current produced by many channels or for the individual current produced by a single channel (Fig. 5). This potential implies a selectivity of Na^+ to Cl^- of about 4:1. Essentially the same result is obtained with gradients of KCl, indicating little discrimination by the channel between K^+ and Na^+; the absence of a significant bi-ionic potential for KCl/NaCl confirms this. The channel also admits divalent cations; in a fivefold gradient of $CaCl_2$ (20 mM:100 mM) the diffusion potential is approximately 2.5 mV (dilute side negative), indicating a slight preference for Ca^{2+} over Cl^-.

The colicin molecule itself forms the channel

Addition of colicin K preparations to one side of planar phospholipid bilayer membranes induces the formation of strongly voltage-dependent, relatively nonselective channels. It is necessary to establish that these channels are not produced by a contaminant in the preparations, rather than by the colicin itself, because the actual number of channels induced in the membrane represents a small fraction of the number of molecules added to the aqueous phase. [This low efficiency is not surprising; it is generally seen with channel-forming molecules (such as gramicidin A) added to the aqueous phase, and probably results from slow kinetics of insertion into the membrane as well as nonspecific adsorption to other surfaces.]

We think it is very unlikely that a contaminant produces these channels. First, these channels are obtained from two separate preparations of colicin K, including a very pure sample from *P. mirabilis*. Second, we have found that colicins E1 and Ia, which act very much like colicin K on cells[1,2,17], also create voltage-dependent, ion-permeable channels in planar phospholipid bilayer membranes. (Whereas the behaviour of colicin Ia is qualitatively similar to that of colicin K, preliminary experiments indicate that the details of the voltage-dependent step(s) in colicin E1 action may be somewhat different.) In contrast, colicins E2 and E3, whose known targets are DNA and rRNA, respectively[1,2], are without effect on the bilayers—with the following caveat. At colicin E2 concentrations 1,000 times larger than those used in colicin K, E1 or Ia experiments, we obtained comparable channel activity. We suspect that this resulted from a small amount of Ia contamination of the E2 preparation; this is not unexpected, as the bacterial source of E2 also carried the Ia gene (T. Boon, personal communication). Furthermore, the single-channel conductance in 100 mM KCl

(~7 pS) and the kinetics of the 'E2 contaminant' were indistinguishable from those of Ia. Also, J. Konisky (personal communication) has found that E2 has a small amount of Ia-like activity which is neutralised by anti-Ia antibodies. The permeability effects observed with E2 on cells[29] may result from this same contamination. Third, two colicins K, produced by supposedly identical plasmids in *E. coli* and *P. mirabilis*[30,31], differ in their single channel conductances (see above). Two independent laboratories have since found that these two colicins differ in molecular weight as determined by SDS-polyacrylamide gel electrophoresis. Colicin K prepared from *E. coli* has a molecular weight of about 5,000 less than that of colicin K prepared from *P. mirabilis* (S. E. Luria and C. Kayalar; K. Jakes, personal communications). Thus, there is a correlated difference in artificial membrane behaviour and biochemistry.

These findings leave little doubt that the channel activity described in this article is produced by colicin K.

Channel activity explains cellular pathophysiology

We believe that the ability of colicin K to make channels in lipid bilayer membranes accounts for the salient features of its action on bacteria as summarised below. In considering this action, we do not address the question of how the colicin, through interaction with its receptor in the outer bacterial membrane, reaches the plasma membrane[32]. Our analysis depends on its somehow doing this. We expect that colicin K and functionally related colicins (such as E1 and Ia) should be effective on suitably prepared spheroplasts and vesicles of both sensitive and resistant strains. In fact, there are already reports of this[7,12,32–36]. The difficulties encountered in obtaining effects with these colicins on bacterial vesicles may be related to the low sensitivity to colicin action of membranes made from *E. coli* phospholipids (see above), and perhaps one function of the receptors in the outer bacterial membrane is to promote the penetration of these colicins into the plasma membrane.

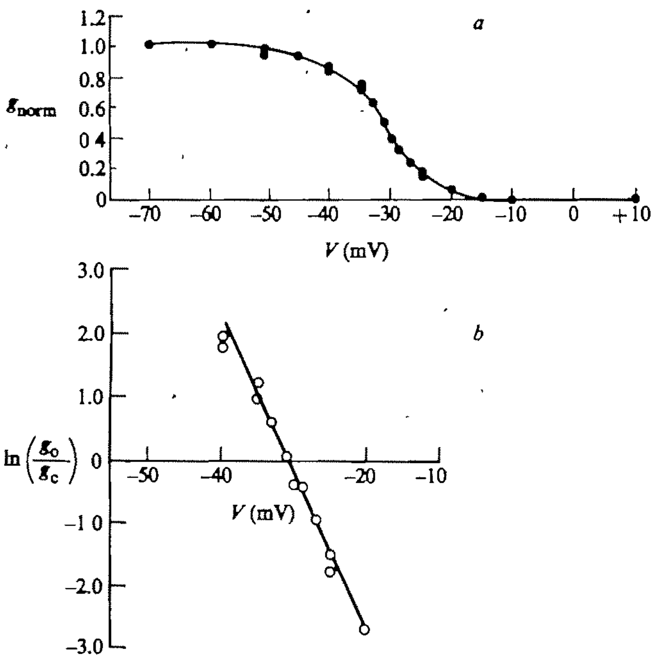

Fig. 2 Voltage dependence of the colicin K-induced conductance *a*, Normalised steady-state, colicin K-induced conductance (g_{norm}) plotted as a function of voltage. (Conductances normalised by setting the conductance at −60 mV equal to 1.) Colicin K (from *E. coli*) was present in the front (*cis*) compartment at 100 ng ml^{-1} Note that the voltage at which $g_{norm} = 1/2$, the 'switching voltage', is −31 mV, and that for voltages > -10 mV, $g_{norm} \sim 0$. The composition of the aqueous solutions are as for Fig. 1. *b*, Plot of ln g_0/g_c against voltage, where g_0 is the fraction of channels in the open (conducting) state, and g_c is the fraction of channels in the closed (nonconducting) state. This is a replot of the data from (*a*); see ref. 25 for details. Note that the points lie on a straight line, and therefore the data are consistent with the Boltzmann relationship:

$$g_0/g_c = \exp\left[-nq(V - V_0)/kT\right]$$

From the slope of the line we see that g_0/g_c (the ratio of the number of open to closed channels) changes *e*-fold for every 3.7 mV. Thus *n* in the above equation is 6.9, suggesting that approximately 7 'equivalent gating charges' are involved in switching a channel on and off. From the intercept of the line with the abscissa, we find that V_0, the switching voltage, is −31 mV. (In over 30 membranes, the value of *n* was consistently between 5 and 7; V_0 is usually around −30 mV, but occasionally values as high as −60 mV have been observed.)

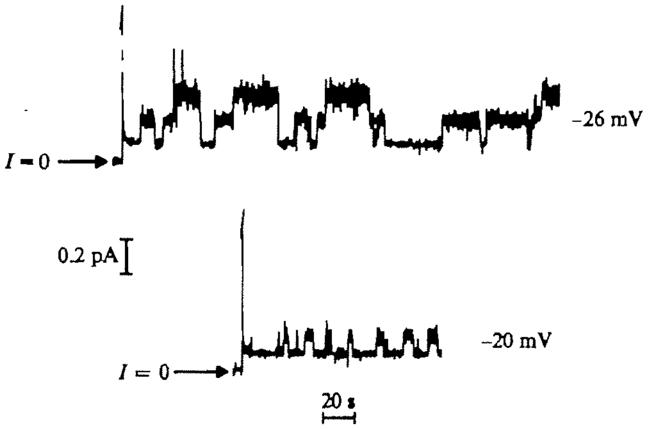

Fig. 3 Current (conductance) fluctuations due to the presence of two colicin K channels in the membrane The large transients mark the times when the voltage was switched from 0 mV to the designated values The conductance of a single channel in the 500 mM KCl solution is about 7.5 pS and is voltage independent. (The size of the current fluctuations is directly proportional to the applied voltage and hence is smaller at −20 mV than at −26 mV.) Note that at −20 mV ($V > V_0$) the channels tend to remain off. At −26 mV ($V \sim V_0$) there are times when both channels are on, one is on, and both are off—with a mean of about 1 channel on. For large negative voltages ($V \ll V_0$) both channels are on most of the time (data not shown). Colicin K was from *E. coli*. The membrane separates identical salt solutions consisting of 500 mM KCl + 5 mM $CaCl_2$ + 1 μM EDTA + 5 mM MES (all adjusted to *p*H 6.1 with KOH)

Ion flux and single hit killing

An early effect on cells of E1 type colicins is the promotion of ion flux[10,12–17]. At low colicin K multiplicity, the rate of potassium efflux from cells suspended in NaCl is directly proportional to colicin concentration; a single active molecule depletes a bacterium of 90% of its potassium in about 10 min[15]. Implicit in this net loss of potassium is an influx of cations (in this case Na^+) and/or an efflux of anions (perhaps Cl^-).

The properties of the colicin K channel observed on planar phospholipid bilayer membranes account for the *in vivo* flux data. The poor ion selectivity of the channel permits sodium and chloride, as well as potassium, movement. Furthermore, the magnitude of the channel conductance is consistent with the rates of potassium efflux observed by Wendt[15], who suspended cells in 20 mM NaCl. The internal potassium concentration of the cells is about 200 mM (ref. 37). Given the selectivity of the colicin channel, it is likely that in Wendt's experiments the membrane potential of the bacteria very shortly after the insertion of colicin channels was around −58 mV. In these conditions we calculate an initial rate of potassium efflux through the colicin K channel (from *Proteus*) of approximately 10^{-18} mol s^{-1}, in agreement with Wendt's[15] data, which translate into an initial rate of potassium efflux of around 5×10^{-19} mol s^{-1} per killing unit. The linear dependence of conductance on colicin concentration (Fig. 4) is also consistent with Wendt's results.

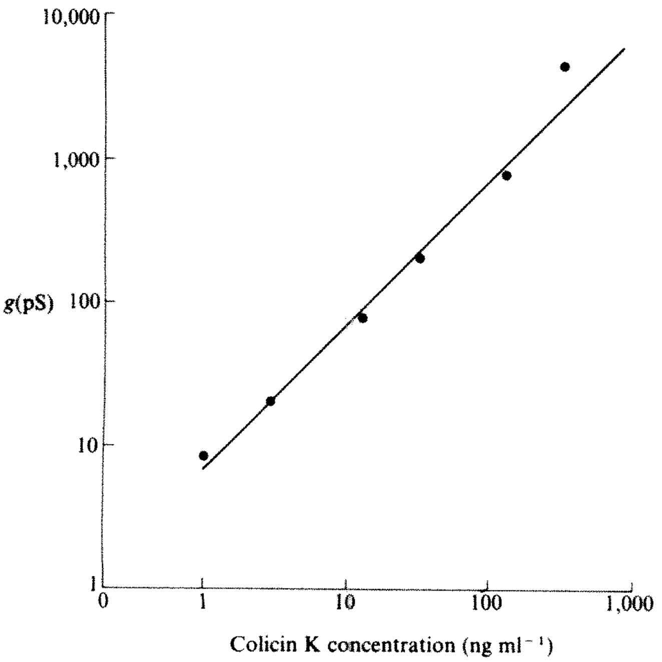

Fig. 4 Double logarithmic plot of steady-state, colicin K-induced conductance against colicin K concentration. The data were obtained on a single membrane at an applied voltage of −70 mV, with the colicin concentrations as indicated. (At this voltage the steady-state conductance has achieved a maximum value; thus the conductance plotted is the maximal conductance.) The line is drawn with a slope of 1. Conductance, and hence the number of channels, increases linearly with colicin K concentration, suggesting that each voltage-dependent channel is formed by one colicin molecule. The composition of the aqueous solutions is the same as for Fig. 1. Colicin K was from *P. mirabilis*.

A remarkable feature of colicin action is single-hit killing[8,18–20]. For colicin K, this feature arises because one poorly ion-selective channel of a few picosiemens conductance can deplete the cell of potassium, magnesium, and other small ions within a few minutes. We do not concern ourselves here with the details and sequence of events leading to cell death following changes in the internal ionic composition (for example, inhibition of macromolecule synthesis, loss of transport systems, drop in ATP levels[1,2]). Interestingly, however, *E. coli* survival following treatment with colicins K or E1 is greater in media containing high potassium and magnesium concentrations[38].

Depolarisation and disruption of active transport

A range of active transport systems are disrupted following treatment of cells with colicins of the E1 type[3,4,39]. This phenomenon is closely related to their ability to discharge the 'energised state' of the membrane[1–7], which occurs without induction of measurable proton flux[6,7,10]. According to the chemiosmotic theory, bacteria use the energy of oxidation to pump protons out of the cell[5]. The energy from the resulting membrane potential difference and *p*H gradient is used, together or separately, to drive a variety of active transport systems[5,40]. The energised membrane state may therefore be disrupted by discharging either the membrane potential or the *p*H gradient.

On the one hand, it is clear that the colicin channels described here would at least partially depolarise the membrane and hence disrupt active transport; the channels are poorly selective among cations and are significantly permeable to anions. Furthermore, numerous studies on bacterial cells and vesicles are consistent with membrane depolarisation[6,7,33,41–45]. On the other hand, given the low activity of protons in the medium (~10^{-6} M) and the enormous internal buffering capacity of the bacterial cell, the colicin K channel should not significantly dissipate any preexisting *p*H gradient as a primary effect. The internal buffering is such[46] that it would require the entry of enough protons to bring the internal concentration to 50–100 mM (assuming no buffering) to produce a change of one *p*H unit. Recent measurements of the *p*H gradient in cells exposed to colicins K and Ia are in agreement with this expectation[6,7,45].

Protection by uncouplers

The normal bacterial membrane potential[5] is of the proper sign and magnitude to open the colicin K channel. Cells are protected from colicin K action by treatments or agents (such as FCCP) which depolarise the membrane[16,18,21]. We suggest that channel closure at low membrane potentials (Figs 2 and 3) is the basis for this protection. (This, of course, does not explain protection from colicin E2 and E3 action by these agents[12,47].) One possible implication of our findings is that the colicin channel might depolarise the cell so severely that the channel would close. More definitive measurements of *in vivo* membrane potentials will be required to establish the likelihood of this possibility.

Colicin K and electrophysiology

The finding that colicin K creates voltage-dependent channels in lipid bilayer membranes opens a new and potentially important avenue of research into the physico-chemical mechanisms underlying the voltage dependence of channels in excitable membranes (for example, nerve and muscle). Colicin channels offer several advantages for investigation. (1) The protein can be highly purified in large quantities. (2) Genetic selection for modified molecules is possible; indeed, we have already noted that colicins K from *P. mirabilis* and *E. coli* differ somewhat both chemically and functionally. (3) The unidirectional orientation of colicin K in the membrane, as evidenced from the voltage dependence, makes possible one-sided modification of the colicin by standard methods of protein modification. This offers a potent technique for dissecting molecular function. (4) The availability of a series of bacteriocins that may form voltage-dependent channels similar to those created by colicin K permits a comparative study of channel formers. In addition to colicins E1 and Ia, which are already identified, other likely candidates are colicin Ib, colicin A, *Staphylococcus* bacteriocin 1580, colicin S.8 and *Serratia* bacteriocin JF246 (ref. 2).

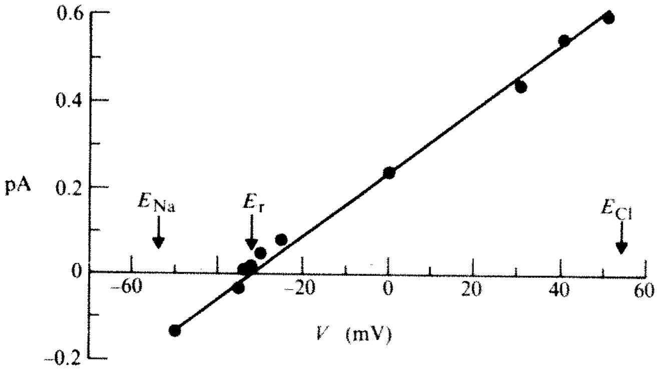

Fig. 5 Ion selectivity of the colicin K channel as determined from the reversal potential of individual channels. Across the membrane is a 10-fold gradient of NaCl concentration, which corresponds to about an 8.3-fold gradient in NaCl activity. The rear compartment contains 500 mM NaCl + 2 mM $CaCl_2$ + 1 μM EDTA + 2 mM MES (*p*H 6.1); the front (ground) compartment contains 50 mM NaCl + 2 mM $CaCl_2$ + 1 μM EDTA + 2 mM MES (*p*H 6.1). A very low concentration of colicin K from *E. coli* was added to the front compartment, and single-channel current jumps, such as shown in Fig. 3, were observed. The size of the current jumps is plotted as a function of membrane potential. The current jumps 'reverse' direction at $V = -33$ mV, closer to E_{Na} (≈ -54 mV), the sodium equilibrium potential, than to E_{Cl} ($\approx +54$ mV), the chloride equilibrium potential, thus showing that the channels are more permeable to Na^+ than to Cl^- by a factor of about 4.

We thank Dr K. Jakes for colicin E1 produced by *E. coli* W3110 (col E1), colicin E2 produced by *E. coli* E2TR2 (strain from P. Fredericq) and colicin E3 produced by *E. coli* W3110 (col E3); Dr S. E. Luria for colicin K produced by *E. coli* K235 and colicin E1 produced by *E. coli* LA779; Dr J. Konisky for colicin Ia produced by *E. coli* W3110 (col Ia − CA53); and Dr M. Jesaitis for colicin K produced by *P. mirabilis*. We also thank Drs Jakes and Luria, and Mr M. Weiss for discussions. Space density evolution of quasars

ATTEMPTS to obtain interesting cosmological information from the study of quasars have been thwarted by the apparent large spread in quasar luminosities so that the conventional Hubble plot produces a scatter diagram[1]. Several authors[2–4] have used an absolute magnitude–redshift diagram to provide a standard candle and hence improved the Hubble diagram. However, little work has apparently been done on using the $(M, \log z)$ plot as a cosmological indicator in its own right, in place of the Hubble diagram. It is shown here that although evolution may be zero, the uncertainty in the quasar luminosity function allows an upper limit on the quasar space density.

Figure 1 shows the $(M_v, \log z)$ plot of quasars from the catalogue of Burbidge *et al.*[5], which were chosen to have $z \leq 2$ and good photometry. The following assumptions have been made. First, quasar redshifts are of cosmological origin so that redshift is a valid indicator of distance, thus[6]

$$m = M + 5 \log D(z) + \text{const} \tag{1}$$

$$D(z) = \frac{1}{q_0^2}\{q_0 z + (q_0 - 1)((1 + 2q_0 z)^{1/2} - 1)\} \tag{2}$$

Second, the Universe can be modelled by a zero cosmological constant, zero pressure Friedmann cosmology. Third, $q_0 = 1$ has been assumed for Fig. 1, but this will be shown not to be essential.

Figure 1 shows that the luminosity of the brightest object at a given redshift is a smooth function of redshift, as has been observed by others[2,3,7]. We propose that the upper envelope is due to a statistical sampling effect identical to the Scott effect[8], which is, as the number of objects in a sample chosen from a given luminosity function increases, the brightest object moves towards the bright end of the distribution, thus as z increases the volume of space sampled increases, as does the number in the enclosed sphere, so that the luminosity of the brightest object in the sphere can be expected to increase. This has been suggested recently by Sramek and Weedman[7]. This theory therefore provides a functional relationship between the luminosity of the brightest object and redshift, which should reproduce the upper envelope in the $(M, \log z)$ plot, given by

$$L_{\max}(z) = f(N_z) \tag{3}$$

The model is characterised by the following assumptions: (1) the space density of quasars is constant at a given epoch, that is the cosmological principle holds. (2) Quasars are distributed according to the normalised luminosity function

$$N(M)\,\mathrm{d}M = N_0 \gamma\, \mathrm{e}^{\gamma M}\, \mathrm{d}M \tag{4}$$

where N_0 is the number in the sample, M is the absolute magnitude and γ is a parameter to be determined observationally. This exponential function in magnitude is equivalent to a power law function in luminosity, and has been discussed elsewhere[8–11]. (3) If N_0 objects are chosen from a distribution $\mathrm{e}^{\gamma M}$ then the value of M for the brightest object, $M_{\max}$, is given by

$$N_0 = \mathrm{e}^{-\gamma M_{\max}} \tag{5}$$

This result can be derived as follows. The normalised distribution in $N_0 \gamma\, \mathrm{e}^{\gamma M}$. It is now postulated that the brightest object is situated where $\int_{M_{\max}}^{-\infty} N_0 \gamma\, \mathrm{e}^{\gamma M} = 1$, that is where the number of objects expected in the tail of the distribution is one, from which equation (5) follows. (4) If density evolution exists it can be characterised by

$$\rho(z) = \rho_0\, \mathrm{e}^{\alpha\tau} \tag{6}$$

where τ is the look-back time to redshift z and ρ_0 is the local

0028-0836/78/0276—0163$01 00

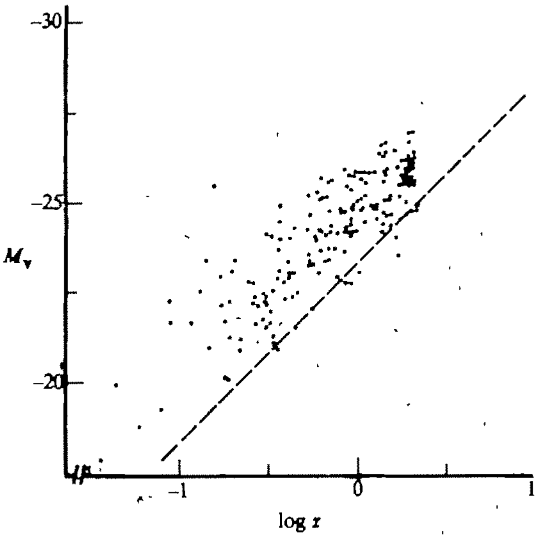

Fig. 1 Absolute magnitude of Burbidge quasars for $q_0 = 1$, as a function of log z. Dotted line shows $m_v = 19$ locus.

density. This exponential law has been discussed by several authors[9,10,13].

The model therefore gives

$$M_{\max} - M^0 = -\frac{1}{\gamma}\ln N(z) \qquad (7)$$

with

$$N(z) = \int_0^z \rho(z)\,\mathrm{d}V \qquad (8)$$

where M^0 is a luminosity cut-off to avoid divergences. The volume of space out to z is calculated from the equations given in ref. 6.

From equation (7) it follows that for low redshift, where cosmological and evolutionary effects are small

$$M_{\max} - M^0 = -\frac{1}{\gamma}\ln \rho_0 \frac{4}{3}\pi\left(\frac{zc}{H_0}\right)^3 \qquad (9)$$

assuming the linear Hubble law, $R = zc/H_0$. Thus the upper envelope in the $(M, \log z)$ plot has a gradient $-6.9/\gamma$ at low redshift. Hence the slope at low z is determined by the index of the luminosity function. Several values of luminosity function index have been given ranging from the high value[7,9] $\gamma = 1.7$ to the low value of 1.1 (ref. 11). For the present purposes, a value of 1.4 ± 0.3 has been taken. It is to be expected that the luminosity function will be improved on in the future.

Fig. 2 Data from Fig. 1 with theoretical upper envelopes superimposed for $\alpha = 0$, 2 and 10 (see text for definition of α).

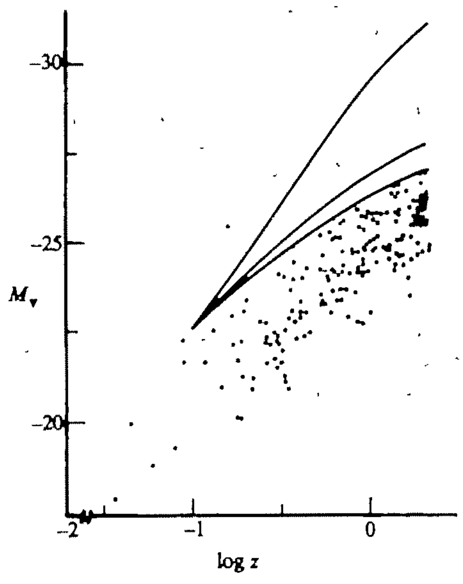

Figure 2 shows the data of Fig. 1 with three theoretical curves superimposed. The lower curve is that for zero evolution, and it can be seen that this calculation reproduces well the observational upper envelope. If a different value of the luminosity function index γ is used, it will be necessary to introduce space density evolution, as discussed by Setti and Zamorani[11]. Thus the uncertainty in γ leads to an uncertainty in evolution. The result obtained for the rate of space density evolution for $q_0 = 1$ is $\alpha = 0 \pm 2$.

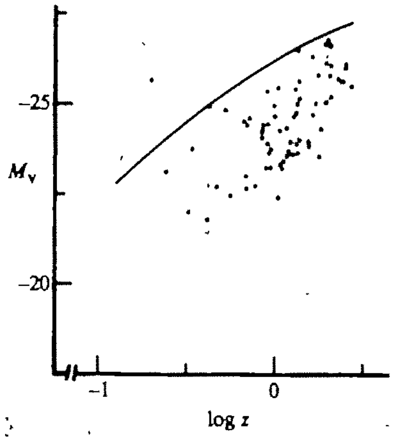

Fig. 3 Absolute magnitude of complete sample of Parkes quasars for $q_0 = 1$, as a function of log z. The theoretical upper envelope for $\alpha = 0$ (no evolution) is superimposed

Table 1 compares the upper limit $e^{2\tau}$ with other evolution laws, where it can be seen that the present result gives much slower evolution. The effect of evolution on the upper envelope is shown in Fig. 2 for $\alpha = 2$ and 10, the latter being comparable to the $10^{5\tau}$ law of Schmidt[9,10]. It seems important that if the luminosity function is as flat as found by Setti and Zamorani ($\gamma = 1.1$) then evolution in a negative sense is implied, that is fewer objects in the past, but still at a slow rate. The dependence of the best-fit value of α on q_0 is:

q_0	0	0.5	1	2
α	1	0.5	0	−0.5

It can be seen from equation (9) that the zero point of the theoretical curve is determined by H_0 and ρ_0, the local space density quasars. Assuming $H_0 = 50$ km s^{-1} Mpc^{-1} this leads to a value of ρ_0, which has been given in Table 2, where $\rho_0(> M^0)$ is the space density of objects brighter than M^0 and ρ_0 diff. is the differential luminosity function scaled to the local space density, that is the number of objects per Gpc^3 with magnitude in a unit range about M^0. The results agree with those of Sramek and Weedman to within a factor of 2, at the bright end.

The Scott effect, which has been the basis of this letter, has had an important influence on previous determinations of quasar evolution. Apparently the Scott effect will mimic evolution by providing an excess of luminous objects at high redshift, thereby biasing the V/V_M test in exactly the same way as evolution. The effect will also show up in number–magnitude counts by simulating a 'local hole'[12]. Hence it seems that what has previously been interpreted as evolution is just the result of the statistical space-sampling effect discussed above.

A further point is the behaviour of the curve beyond $z = 2.5$, where the observed number of quasars is very low (Smith[14]). As well as the important fact that space volume is a very low function of z, so that there is very little space volume between $z = 2.5$ and 3, it now seems that the space density is much lower than previous evolution laws have implied, which makes the expected number of objects even smaller. In addition, as Fig. 2 shows, the absolute magnitude of the brightest quasar remains nearly constant beyond $z = 2.5$, so that the objects apparently become increasingly faint with increasing redshift. This situation has been discussed by Carswell and Smith[15] who found that the observed number of quasars of high redshift can be accounted for assuming zero evolution. Thus it seems that the era of quasar formulation has not yet been found.

Table 1 Evolutionary laws

z	τ	$(1+z)^6$	$10^{5\tau}$	$e^{2.0\tau}$
0	0	1	1	1
0.2	0.269	3	22	1.7
0.5	0.495	11.4	298	2.7
1	0.683	64	2,600	3.9
2.0	0.832	729	14,400	5.3
3.0	0.892	4096	28,840	6.0
∞	1	∞	100,000	7.4

The Burbidge catalogue of QSOs has been used in the present application of this technique because it is the largest body of data available. However, due to the heterogeneity of this catalogue, selection effects might be important. It is difficult to see where such effects might arise as they would have to be redshift-dependent to affect the present analysis and because most of the objects used are radio sources, redshift dependent effects should be negligible. In addition, redshift dependence in the optical identification is unlikely, as it is the brightest objects at each redshift which are of concern and the apparent magnitude of these changes only slowly with redshift, in the redshift range used here. In any case, it was felt important to test the method on a complete and homogeneous set of data. Figure 3 shows the (M_v, log z) diagram for Parkes objects from the Wills and Lynds[13] catalogue, where it can be seen that the result derived from Fig. 1 is unchanged. In this work k-corrections have been neglected as they are expected to be small[16]. A larger sample of low redshift ($z \leqslant 0.1$) quasars would be very valuable to improve the determination of slope and zero-point. It has been suggested[17] that steep and flat radio-spectrum quasars differ in evolutionary properties, and the present approach should be able to discriminate between the two species on those grounds, provided a good enough sample of data can be acquired.

We have found that previous determinations of quasar space density are subject to a statistical sampling effect depending on space volume. The present result is that evolution may be zero but the uncertainty in the quasar luminosity function allows an upper limit of $\rho(\tau) = \rho_0 e^{2\tau}$.

That the present method works at all must favour the cosmological nature of quasar redshifts. Also it is predicted that absolute magnitude of the brightest object at a given redshift increases very slowly beyond $\sim z = 3$ so that objects beyond that become increasingly faint and more difficult to detect.

Table 2 Local space density of quasars

Micropulsations observed by whistler-mode transmissions

DUCTED whistler-mode signals from VLF transmitters are typically Doppler shifted by ~0.1 Hz from the transmitter frequency. This Doppler shift has been attributed to motion of the ducts (geomagnetic field-aligned enhancements of plasma density) and measurements of the Doppler shift of NLK (18.6 kHz) signals have been used to observe relatively steady duct drifts over several hours[1,2], as well as duct oscillations in the Pc4–5 range[3]. We report here duct oscillations in the Pc3 range of a 6.6 kHz signal from a transportable VLF transmitter in Alaska, which was received at Dunedin, New Zealand[4]. Two events were observed, about six hours apart, as shown in Figs 1 and 2. For both these events, comparisons between the Doppler oscillations and ground magnetograms fit very well with current ideas about micropulsations.

Strong whistler-mode signals were received on 10 September 1973 from 13.00 to 13.30 UT showing both linear and nonlinear amplification as reported elsewhere[5], and from 19.40 to 20.30 UT where only linear amplification occurred. Various transmission formats were sent, and the received phase at Dunedin was compared with an accurate reference phase using a 'phasogram'[5]. This is a plot, made on moving film, of phase difference against time. Thus by measuring the slope, the frequency offset, Δf, is obtained as a function of time.

Figure 1*a* shows this frequency offset for the interval 13.14–13.27 UT. A sinusoidal function was fitted to the data by the method of least squares, giving a period of 94.0±0.4 s. At 13.00 UT one-hop delays were measured to be 1.500 and 1.455 s (ref. 5) indicating transmission in two closely spaced ducts. Dispersion analysis of whistlers occurring simultaneously with the above group delays showed the two ducts were at $L = 3.88$ and $L = 3.77$. However, during the period analysed only the signal with the 1.455 s delay was apparent, indicating that the observed oscillations occurred along the $L = 3.77$ field line.

Figure 1*b* shows an enlarged portion of the **H** trace from a magnetogram recorded at Campbell Island ($L = 4.0$), which is situated near the foot of the $L = 3.8$ field line (**H** is much stronger than the **D** component). Pulsations of 94 s period with amplitude ~1.3 nT are clearly present (all amplitudes are mean-to-peak).

Magnetic field measurements in the form of $|\partial \mathbf{B}_z/\partial t|$ were also made at Dunedin ($L = 2.7$) by recording, on the same magnetic tape as the VLF data, the voltage induced in a horizontal loop[6] of $\sim 5\times 10^4$ m^2. This enabled accurate synchronisation between magnetic and VLF data. A very weak 94 s pulsation was found by spectral analysis.

As the periods of the Doppler and magnetic oscillations were the same, the oscillation was meridional and most likely fundamental with an antinode of motion at the Equator[3]. This is supported by calculations of the resonant frequency of oscillating field lines in a dipole field and variable plasma density[7], where the fundamental period at $L = 3.8$ (colatitude = 30.9°) is ~90 s.

The phase path and hence phase time, T_p, varies with latitude, tube content, and maximum equatorial displacement of the duct from its mean position, caused by the distortion of the dipole field. Andrews *et al.*[8] showed that the electron content of the duct remains constant for Doppler fluctuations with periods <30 min. Hence we can assume that the Doppler shift is entirely due to duct movement (where magnetic field strength, and hence refractive index and path length, change). The Doppler oscillation is assumed to be due to the radial component of motion because the azimuthal component has little effect on the phase path[3].

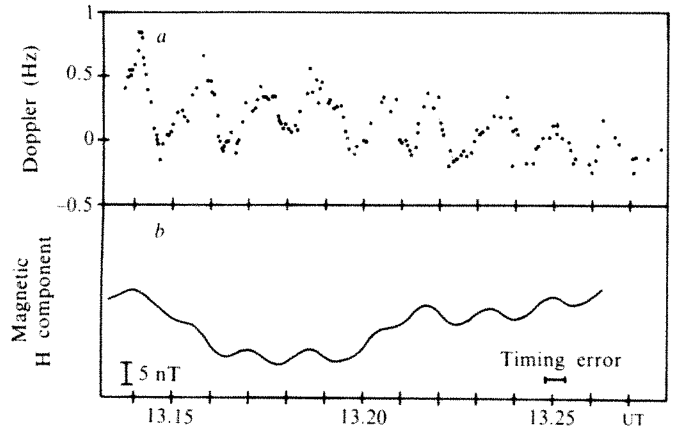

Fig. 1 *a*, Doppler shift of 6.6 kHz whistler-mode signal plotted against time for 13.14–13.27 UT, 10 September 1973. The Doppler shift is obtained by phase analysis as described in ref. 5. *b*, Magnetic **H** component scaled from a Campbell Island ($L = 4$) magnetogram. Absolute timing is ±15 s on the magnetogram. Magnetic variation $|\partial \mathbf{B}_z/\partial t|$ at Dunedin also shows a very weak 94 s pulsation.

The rate of change of phase time, dT_p/dt, equals the fractional change in frequency, $-\Delta f/f$. In its effect on the VLF wave, a small change in equatorial displacement, d (with a node near the Earth's surface) is similar to a small change in L-value of the duct in an undistorted dipole field, as the whistler-mode wave spends most of its time near the Equator. Thus by calculating the variation of phase time with latitude in a suitable model magnetosphere, we can calibrate dT_p/dt in terms of an equatorial duct velocity, v_0, given by:

$$v_0 = R_0 \frac{dL}{dt} = -R_0 \frac{dL}{dT_p}\frac{\Delta f}{f}$$

where R_0 = Earth's radius. The peak displacement, d, is obtained by integrating v_0 over one quarter period. A model magnetosphere with a steep equatorial electron density profile proportional to L^{-5}, as the duct is near the plasmapause, gives $dT_p/dL = -0.34$ s and $d \sim 16$ km. An estimate of the wave magnetic field can be obtained from this using a simplified two-dimensional model of a transverse standing Alfvén wave. The wave magnetic field, $\mathbf{b}_x$, in the North–South plane above the ionosphere is given by:

$$\mathbf{b}_x = \mathbf{B}\frac{\partial \xi_x}{\partial z}$$

where $\mathbf{B}$ = local magnetic field, ξ_x is the meridional displacement and z is distance along a field line from the ionosphere. Assuming a dipole field and that $\mathbf{b}_x$ varies sinusoidally along the field line, with a node at the Equator, we get a displacement of 7.9 km nT^{-1} at $L = 3.8$. Hence $\mathbf{b}_x$ is just above the ionosphere (1,000 km) ~ 2 nT. This is slightly greater than the **H** component on the Campbell Island data.

Note that the Doppler oscillation is superimposed on a slowly varying Doppler shift. If this mean shift is also due to duct drift, then perhaps the damping of the oscillation in Fig. 1*a* can be interpreted as spatial attenuation as the duct drifts inwards from the resonant latitude. Time damping is unlikely as the Campbell Island data show no such damping in Fig. 1*b*. From the least-squares fit to Fig. 1*a*, the time for the amplitude to be halved is 408 s. The average Doppler shift over this period gives a net equatorial drift velocity of 0.45 km s^{-1}, so the half-width of the resonance region is ~180 km. This supports models with a sharp amplitude peak at a particular latitude[9].

The one-hop group delay for the signal in Fig. 2*a* was 1.150 ± 0.005 s which, when combined with whistler analysis gives the duct location at $L = 2.85 \pm 0.02$. Note that the frequency offset is much smaller than in Fig. 1*a*; the period of oscillation is 60.3 ± 0.5 s. Magnetic variation at Dunedin Fig. 2*b* shows pulsations of this period and of about 0.2 nT amplitude very clearly. The Campbell Island magnetogram also showed barely resolved 60-s oscillations of about 0.4 nT amplitude on the **H** trace.

Calculations using a magnetospheric model with a typical equatorial density variation proportional to L^{-4} gave $dT_p/dL = -0.53$ s at $L = 2.85$, implying a peak displacement of ~1 km for the field line oscillation. This corresponds to a 0.4-nT disturbance just above the ionosphere.

Resonant field line calculations show[7] that, for a fundamental oscillation of 60 s period, $L \approx 3.4$. Hence this observation is from below the resonant latitude and is consistent with the relatively low amplitude observed in the magnetosphere.

Cross-correlations of the digitised Dunedin magnetic variation $|\partial \mathbf{B}_z/\partial t|$ with Doppler shift for both intervals (Fig. 3*a*) show they are in phase quadrature. (Timing accuracy at Campbell Island was insufficient to allow phase comparisons with Dunedin.) The wave in the resonance region is most likely to be linearly polarised as Campbell Island **H** and **D** components seemed to be in phase. We assumed circular polarisation[3] for the Dunedin magnetic data as it was far from resonance in both cases. Theoretical calculations show[9] that the phase of $\mathbf{b}_x$ above

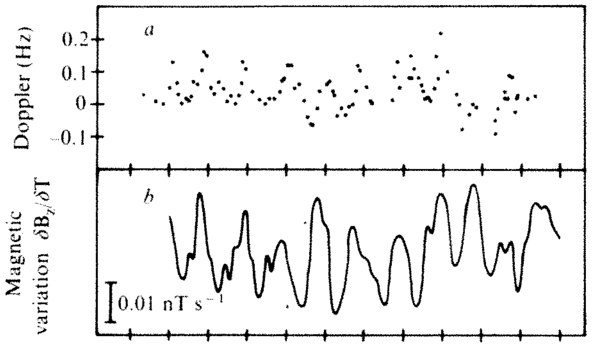

Fig. 2 *a*, Doppler shift observed in the interval 19.44–19.54 UT, 10 September 1973. Note the smaller amplitude than in Fig. 1*a*. *b*, Magnetic variation $|\partial \mathbf{B}_z/\partial t|$ recorded at Dunedin simultaneously. Pulsations of ~0.2 nT are very clear whereas they are barely resolvable on the Campbell Island **H** trace (<0.4 nT).

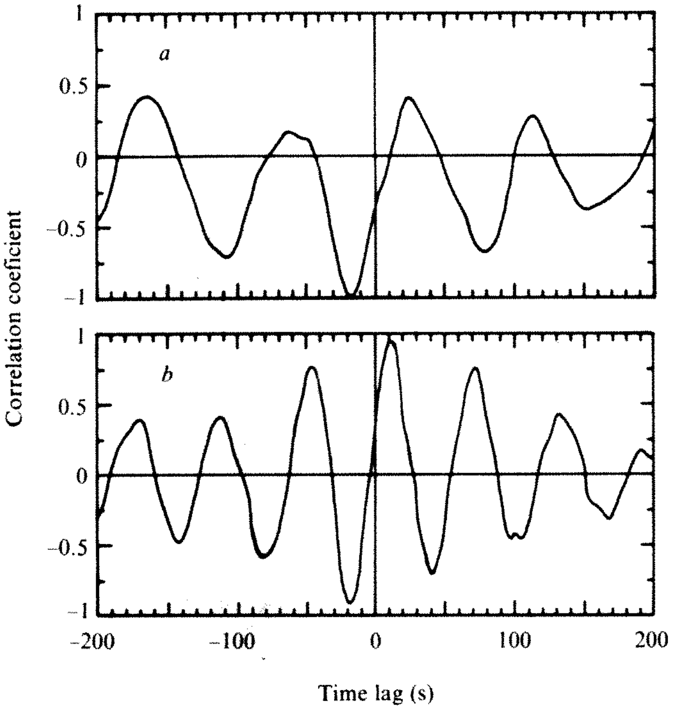

Fig. 3 Cross-correlation between Doppler shift (Δf) and magnetic variation $|\partial \mathbf{B}_z/\partial t|$ recorded at Dunedin. Positive lag means magnetic variation leads Doppler shift. *a*, For the interval 13.14–13.27 UT a lag of 24 s is present, equal to a quarter period. *b*, The lag is 10 s for the interval 19.44–19.54 UT.

the ionosphere is relatively constant with latitude including the resonant latitude. Hence the cross-correlations are consistent with a phase rotation of 90° through the ionosphere as f and $|\partial \mathbf{B}_z/\partial t|$ are in phase quadrature with $\mathbf{b}_z$ and $\mathbf{B}_z$ respectively. This assumes $\mathbf{B}_z$ has mainly the phase of the **H** component.

The above observations show that by phase tracking whistler-mode signals, duct oscillations in the Pc4 (and probably Pc3) range can add new information to existing ground (and satellite) micropulsation data. Indeed the fine latitudinal structure of the resonance region in the magnetosphere could not be easily obtained by other means in these latitudes. At high latitudes ($L \sim 6.3$) this structure has been studied by auroral radar[10] and estimates of the width of the resonance region in terms of $\Delta L/L$ are about four times (A. D. M. Walker, in preparation) our estimate for $L \sim 3.8$.

We thank Dr H. C. Koons and M. H. Dazey of the Aerospace Corporation for the VLF transmissions, and Drs N. R. Thomson, M. K. Andrews and Professor A. D. M. Walker for helpful discussions. This work was sponsored in part by the New Zealand University Grants Committee. The Campbell Island magnetic data were supplied by the Christchurch Geophysical Observatory.

Triplet state resonance Raman spectroscopy

AN important objective of theoretical photochemistry is to describe the interplay between the different decay channels of molecules in electronic excited states[1,2]. Detailed information on the potential energy hypersurface is required to specify the molecular dynamics in terms of saddlepoints and activation energies along the reaction coordinate. Excited electronic states differ from the ground state because of the changes in the electronic distribution within the molecular framework. These changes are accompanied by changes in bond orders, force constants of vibration and dissociation energies. Vibrational spectra of excited states could be expected to provide important information on changes in frequencies of particular normal modes relative to those of the ground state molecule. Triplet excited states in solution have been studied by many techniques, the most common being flash photolysis in combination with optical absorption spectroscopy. Vibrational spectroscopy has to our knowledge only been reported in a single case, where one vibrational band of the lowest state of deuterated naphthalene generated by steady-state illumination was detected by infrared spectroscopy[3]. Recently, resonance Raman spectroscopy has been established as a powerful technique for studying shortlived species in solution[4]. This technique combines high sensitivity and time resolution with selectivity and structural information. It has been used successfully to study free radicals in solution generated by stopped flow methods[5], electrochemically[6], by pulse radiolysis[4] and recently by laser flash photolysis[7]. Here we make the first report on the resonance Raman spectrum of a molecule in its triplet state generated by pulse radiolysis.

The experimental system has been described previously[4]. Excited states were produced by electron irradiation with a pulse of high energy electrons. Concentrations and kinetics of the transient species were established by optical absorption spectroscopy, and a pulsed dye laser and an optical multichannel analyser coupled to a computer were used to record the resonance Raman spectrum of the transient species.

It is well established[8] that the lowest excited triplet state is formed on electron irradiation of solutions of organic molecules in benzene. The mechanism proposed is the formation of a radical cation–electron pair of a solvent molecule followed by fast recombination into a low-energy excited state, and the subsequent energy transfer to solute molecules exciting these into the lowest triplet state. We investigated a solution of 0.01 mol dm^{-3} of p-terphenyl in benzene. The maximum of the triplet–triplet absorption spectrum was found at 460 nm which agrees with the literature[9], and the wavelength of the dye laser was tuned to approximately this value. The lifetime of the

excited species was 4.4 μs. The concentration of excited states was estimated to be $\sim 1 \times 10^{-4}$ mol dm^{-3}.

The resonance Raman spectra without and with electron irradiation are shown in Fig. 1. Table 1 lists the Raman bands found in the parent *p*-terphenyl molecule and the transient excited state. Characteristic wavenumber shifts occur in going from the parent molecule to the excited state species. Tentative assignments can be made according to the normal coordinate analysis for biphenyl by Zerbi and Sandroni[10].

All bands of the transient species, with the single exception of the 587 cm^{-1} band, are assigned to totally symmetric vibrations, suggesting that A-term scattering[11] predominates. This seems to indicate a substantial change in geometry in going from the lowest to the higher excited triplet state. According to Zerbi and Sandroni the main contribution to the Raman band of the parent molecule at 1,284 cm^{-1} originates from the ring–ring C–C stretching vibration. We believe that this band is shifted upwards by 66 cm^{-1} in the spectrum of the triplet species, which suggests an increasing bond order and a higher degree of planarity in the triplet state compared to the ground state. This result agrees with the literature: Orloff and Brinen[12] conclude from MO calculations of zero-field splitting parameters that there is a striking change in geometry in going from the ground state to the lowest triplet state of the polyphenyl-benzenes, and that a substantial shortening of the ring–ring bond occurs. Wagner[13] suggests on the basis of spectroscopic and quenching results that in the ground state biphenyl is twisted with an interplanar angle of 25°, whereas the triplet state seems to be planar.

We have demonstrated that triplet states can be investigated by resonance Raman spectroscopy. Because of the obvious advantages of this technique compared with absorption spectroscopy, it is expected that it will become a valuable tool in the investigation of shortlived excited states, their structure and kinetics.

We thank Dr R. E. Hester for recording the spectrum of *p*-terphenyl and Jytte Eriksen and Preben Genske for technical assistance. This work was supported by grants from the Danish Natural Science Research Council.

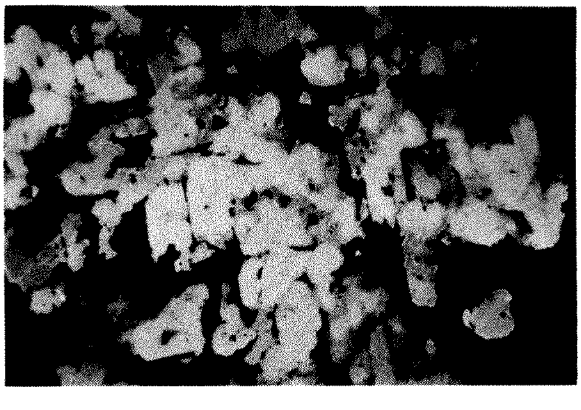
FeNi superlattice formation by corrosion of Santa Catharina meteorite

KNUDSEN *et al.*[1-3] have recently presented evidence from Mossbauer spectroscopy and X-ray diffraction, that an FeNi L1_0 superlattice exists in the taenite of the Cape York and Toluca meteorites. This superlattice, which had previously only been reported in neutron irradiated specimens[4], is thought to have formed during the extremely slow cooling, 1°C Myr^{-1}, of the parent bodies of these meteorites. Here we report briefly on the discovery of the FeNi superlattice in a nickel-rich ataxite, Santa Catharina, and show that in this meteorite the ordering occurred during terrestrial corrosion.

Apart from some large idiomorphs of iron nickel phosphide (schreibersite) and a dispersion of small plates of the phosphide (rhabdite), the Santa Catharina meteorite contains two main microstructural constituents, one of which, the dark etching constituent of Fig. 1, is a face-centred cubic (f.c.c.) taenite containing 30.7 atom%Ni and having lattice parameter $a =$ 3.586 Å. The structure of the light etching constituent has, until now, been uncertain. Thermomagnetic measurements[5] indicated it to be a 55 atom%Ni taenite, but microprobe analysis[6] showed that it contained up to 25 atom% oxygen. We have established that this light etching constituent consists of a dispersion of particles of FeNi spinel, Fe_2NiO_4, ~50 Å thick, in an ordered 53 atom%Ni taenite. The spinel particles comprise between one- and two-thirds (atom fraction) of this constituent. They are, however, too small to diffract X rays coherently and diffraction patterns from this constituent are single crystal patterns from the taenite. Patterns obtained using $Co_{K\alpha}$ radiation contain reflections from all of the {100}, {210}, {211} planes and from planes with higher indices. These reflections indicate that domains of all three orientations of the superlattice, FeNi, are present. The lattice parameter, 3.582 Å, of the ordered taenite is nearly equal to that of the 30.7 atom%Ni taenite and its orientation is the same. The spinel particles can be detected in

Fig. 1 Light and dark etching constituents in the Santa Catharina meteorite. Parts of some specimens consist almost wholly of the dark constituent. Nital etch. ×200.



0028–0836/78/0276—0168$01.00

extraction replicas, by electron microscopy and electron diffraction. They coarsen rapidly on heating and can be resolved optically after 1h at 615 K. Reflections from the spinel particles appear in the X-ray diffraction patterns of specimens heated at 575 K for 1 h.

The terrestial origin of the light etching constituent has been established by observing its formation in samples consisting almost wholly of the 30.7 atom%Ni taenite that were cut from the meteorite and subjected to corrosion at room temperature in water containing a small concentration of chloride ions. Figure 2 shows a section through the light etching constituent produced in a specimen corroded for 35 d. It has been detected in specimens corroded for as little as 5 d. The constituent produced by corrosion is the same in all respects as the natural material; the taenite is ordered and the compositions and electron microstructures are the same.

The mechanism by which this corrosion product is formed will be discussed in more detail elsewhere, but it is evident that the enrichment of the taenite from 30.7 to 53% Ni and the ordering of this phase, requires a degree of atomic mobility not normally available at room temperature. It is likely that this enhanced mobility is attributable to di-vacancies generated at the surface by the preferential dissolution of iron atoms[7]. Such excess vacancies would also permit the ingress of oxygen atoms to form the spinel.

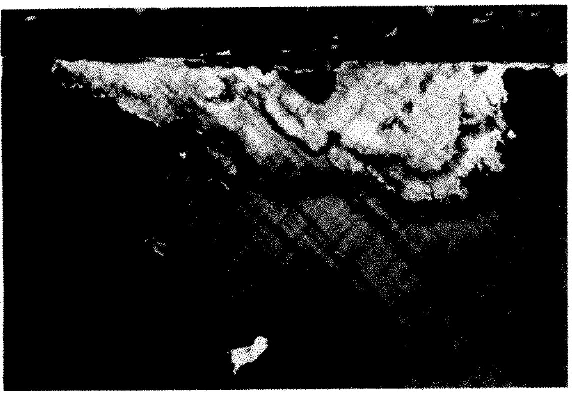


Fig. 2 Light etching constituent produced by corrosion. Nital etch. ×200.

The formation of the $L1_0$ superlattice during corrosion obviously means that care must be taken when using the presence of this superlattice as an indication of the thermal history of meteorites. However, it is not expected that the taenite lamellae in octahedrites would be susceptible to this type of corrosion process while the low nickel kamacite is present. Even when the kamacite has corroded away the high nickel concentrations, which are produced in the outer layers of the taenite during the precipitation of the kamacite, would corrode much more slowly than the taenite of Santa Catharina.

It is curious that the lattice parameter of the nickel-rich ordered taenite in Santa Catharina is the same as that measured by Knudsen *et al.* in Cape York and Toluca. In these meteorites, the taenite lamellae were found to contain a disordered f.c.c. phase as well as the superlattice, the lattice parameters of both phases being 3.582 ± 0.002 Å. Comparison with published parameters[8] showed that the disordered phase contains approximately 28 atom%Ni and it was proposed that these two phases occur in varying proportions in the nickel concentration gradient in the taenite. The concentration gradient is considered to be 'frozen in', but within each volume element short-range diffusion of nickel has permitted the development of the two-phase structure. In this model the two-phase region is identified with the dark etching zone of so-called cloudy taenite observed in many octahedrites, whereas the clear taenite rim is considered to consist almost wholly of superlattice.

Knudsen *et al.* consider that the domains of ordered taenite in the two-phase region have the composition FeNi, but published lattice parameters of iron nickel alloys indicate that ordered taenite with $a = 3.582 \pm 0.002$ Å contains 53 ± 2 atom%Ni. Our microprobe analyses of Santa Catharina confirm that ordered taenite with this lattice parameter contains more than 50 atom%Ni. These analyses indicate that the light etching constituent contains varying proportions of Fe_2NiO_4 and taenite containing ~55 atom%Ni.

It is surprising that a single lattice parameter was observed in the Ni concentration gradients of Cape York and Toluca. The nickel concentration in the taenite at the taenite–kamacite interface is determined by the composition of disordered taenite in equilibrium with kamacite at the temperature at which growth of the kamacite ceased. The concentration of nickel in ordered taenite in metastable equilibrium with disordered 28 atom% Ni taenite is expected to be below this upper limit. Thus, the concentration gradient should contain a two-phase region in which the lattice parameter of the ordered taenite is constant, and a single-phase region, in which the lattice parameter varies between this value and that of taenite in equilibrium with kamacite. The range of nickel concentrations in this single-phase region indicated by the error limits of the parameters measured by Knudsen *et al.* is 53 ± 2 atom%Ni, implying that the lower limit of the clear taenite is at 51 atom%Ni. This conclusion conflicts with other measurements[9,10] which indicate a lower limit of 40 atom%Ni.

Earthquake precursors from Earth tilt observations corrected for rainfall

AN Earth tilt meter at Wellington, New Zealand (lat 41°14′S, long 174°47′E) has been operating since 1972 in old underground tunnels which are about 15 m below the surface. Installation transients, at first of the order of several microradians per year, have decayed slowly and are now about 0.3 μrad yr^{-1}. As is well known[1,2] rainfall and evaporation, in all but very deep sites, usually completely obscure any obvious relationship with tectonic events. Wood and King[3] have made one unsuccessful attempt to deal with this problem but the largest earthquake occurring was only of magnitude 5.2. A new approach, described here, has yielded significant correlations of tilt with two, and possibly three, earthquakes of magnitudes 5 to 6.2. The precursor times are in fair agreement with Rikitake's[4] equation.

Our approach has been to deal solely with monthly mean values of tilt, rainfall and the other meteorological elements involved. After correcting for both the exponential installation transient and average seasonal variation the monthly tilt departure from normal, T_0, correlates significantly with the monthly

0028-0836/78/0276—0169$01.00

rainfall minus evaporation departures, $(R-E)$, for the previous 5 months. This leads to a tilt correction of the form:

$$T\alpha = a(R-E)_0 + b(R-E)_1 + c(R-E)_2 + d(R-E)_3 + e(R-E)_4 + f(R-E)_5 + gt_0 + ht_1 + jP_0$$

where the suffix refers to the nth month before the one in question, t is the monthly mean temperature departure and P that for atmospheric pressure. Meteorological data were supplied by a nearby weather station.

The coefficients a–h were optimised to produce the highest correlation coefficient between the values T_α and T_0. Other possibilities were also tried, like extending the series for more than 5 months into the past, but the highest correlation coefficients obtainable were $r = 0.89$ and 0.83 for the N–S and E–W tilt components respectively. This was done for the entire period of the study, 1974–78, and indicates, for instance, that only $100(1-r^2) = 21\%$ of the N–S variations observed are due to non-meteorological causes, presumably tectonic.

The residual tilt, $T = T_0 - T_\alpha$, is shown in Fig. 1, together with earthquakes of $M \geqslant 5$ occurring near enough to the station to be of significance. Figure 2 shows the epicentres, magnitudes, and dates of all normal earthquakes $M \geqslant 5$ occurring within about 150 km during the period analysed. The NZ Seismological Observatory supplied the seismological data[5].

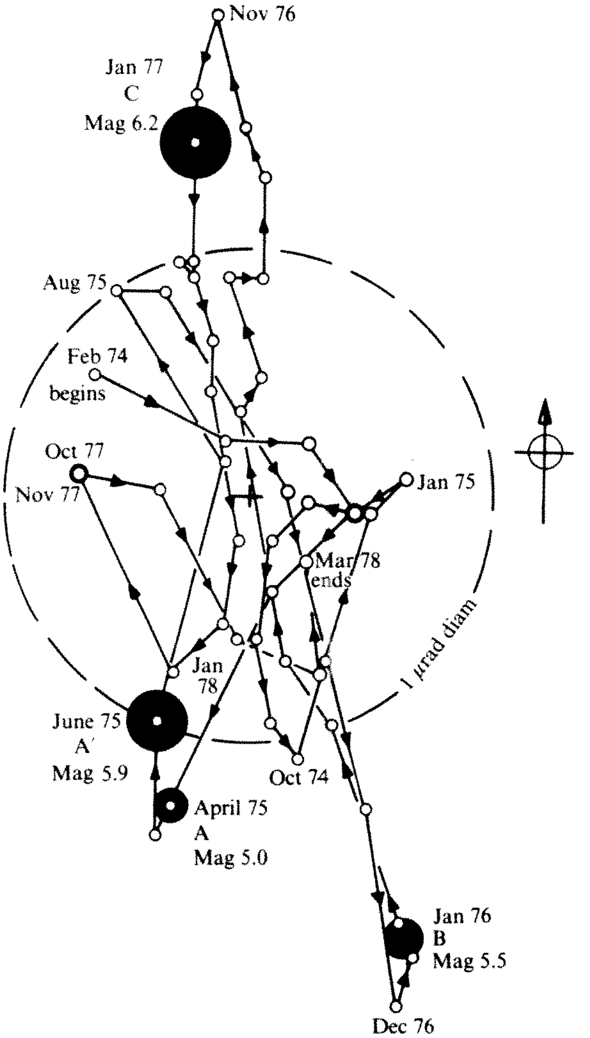

Fig. 1 Wellington Residual Earth Tilt 1974–78. Small open circles are monthly tilt values with only significant months labelled. Large solid circles are significant earthquakes lettered to correspond with Fig. 2.

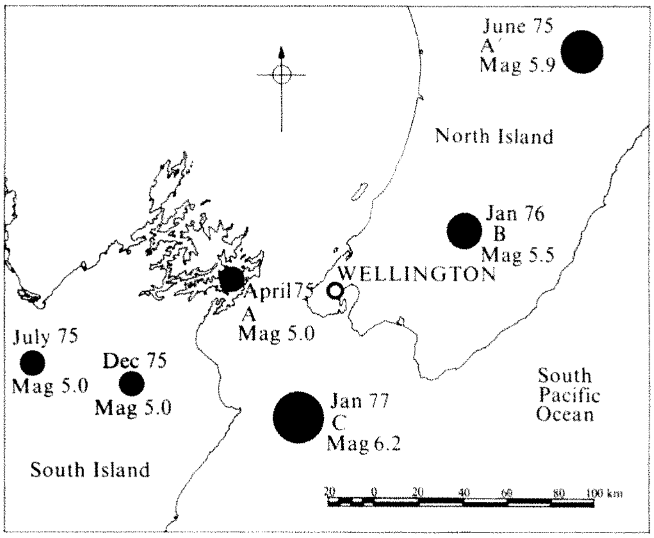

Fig. 2 Epicentres of all normal earthquakes of magnitude $M \geqslant 5$ within about 150 km of the station, during the period covered by Fig. 1. The letters refer to the corresponding earthquakes in Fig. 1.

The fit of the tilt anomalies with the two largest nearest earthquakes labelled B and C is remarkable; in each case the earthquake occurred after the tilt anomaly began to return to normal and the precursor time, while not agreeing exactly with Rikitake's[4] equation, is, nevertheless, longer for the larger earthquake even though this has the smaller anomaly. A change in the direction of tilt a month or so before the earthquake has been mentioned by Scholz *et al.*[6] in connection with Japanese earthquakes. As well as showing this effect it is also to be noted that the anomaly directions tend to be away from the future epicentres.

However, there are three possible interpretations for the first and smallest anomaly peaking in May 1975. First, it might be of no significance since it is only slightly greater than the general random walk background or it could be correlated with either earthquake A or A′. Earthquake A′ was of magnitude 5.9 and, coming in June 1975, would provide a better fit because it was then past the tilt maximum; the tilt direction is also a better fit than for earthquake A, which was smaller and nearer. Earthquake A′ was probably too far away to be detected, however. None of the other normal earthquakes were near enough or large enough to be regarded as significant. One deep earthquake, not shown, had a depth of 128 km, a magnitude of 5.9, and occurred in January 1975 having its epicentre near B. No tilt anomaly at this time is apparent and this is consistent with theories of dilatancy which suggest that a deep earthquake may not produce precursors.

Restricting the situation to normal earthquakes of $M \geqslant 5.5$ within 100 km a statistical analysis based on a Poisson distribution has yielded a probability of 3.1×10^{-3} that the overall agreement is due to chance. Thus the apparent precursory tilts are probably genuine, at least in the two clearest cases. A forthcoming damaging earthquake ($M > 6.5$, say) at a favourably situated epicentre should produce a definite detectable precursory tilt.

I thank Dr A. H. McIlraith for computing the statistical probabilities.

Sea level–air temperature correlations near a coastal zone

A NUMBER of naturally occurring chronometric records, such as the growth rings of trees[1], distribution of pelagic fish scales preserved in anaerobic sediments[2] and the thickness of annual laminations of these sediments[3], have been correlated with time series of climatological variables. I have previously introduced sea level as one predictive variable of diatom abundance[4]; here I propose sea level as another predictive variable which can be used to estimate air temperature near the coast of San Diego (32°43′N 117°10′W) and Los Angeles (33°56′N 118°24′W). Although historical data series of sea level and air temperature have been correlated with several atmospheric and oceanic variables in the past[5], no correlation between them has, as far as I know been reported previously.

The causes of long-term (months, years) variations in sea level have been enumerated by Montgomery[6], and Lizitzin[7]. These are: (1) meteorological (atmospheric pressure, wind, precipitation and evaporation); (2) oceanographic (water density and currents); (3) river discharge; (4) the eustatic contribution; and (5) the nodal tide with the period of 18.61 yr. Factors (3) and (5) can be eliminated for the San Diego region; river discharge is negligible, and the effect of the nodal tide is expected to be very small as one of the nodal lines is located at 35°N (ref. 8), which is very close to the location under study.

Stewart *et al.*[9] investigated data recorded at several stations along the coast of North America and reported that the anomalously warm sea surface temperatures during the 1957–58 period coincided with anomalously high sea levels. Roden[10] verified this finding and reported that there was a significant correlation between monthly anomalies (deviation from long-term mean) of sea level and monthly anomalies of sea surface temperatures. Changes in sea level, during two decades, 1948–57 and 1958–69, have been studied by Namias and Huang[11]. They reported that the largest cause of variation was thermal, accounting for 3.7 cm, followed by the overall dynamic effect, 1.0 cm, and atmospheric pressure differences (the inverted barometer effect) 0.6 cm.

It is also well known that at several coastal stations of North America, including San Diego, sea surface and air temperatures are significantly correlated[12]. These findings are sufficient to hold as *a priori* that changes in sea level should be reflected in air temperatures.

Data plotted in Fig. 1 show that this is the case for both locations. Statistical methods used in obtaining Table 1 can be found in ref. 13. Briefly, average skill index calculated from N number of data points, $S_H(N)$, can be written as the sum of two terms: $S_H(N) = S_T + S_A$ where S_T is the true skill index, and S_A the artificial skill which is due to any error in sample correlations which will lead to an increase of skill above the true skill index, S_T, and depends on the number of data points: $S_A = K/N$ where K depends on time scales. The method of calculating S_H (1.0 = perfect correlation, 0.0 = no correlation) is the same as for calculating the per cent of explained variance, r^2, where r is the correlation coefficient. (For various ways of calculating S_A, see ref. 13). As can be seen in Table 1, skill indices for both locations are significantly greater than the artificial skill indices; that is, they are significantly correlated. Annual anomalies of both variables have been calculated after the effect of their respective trends have been removed.

Table 1 Trends and correlation coefficient (r), skill index, S_H (per cent of explained variance, r^2) and artificial skill, S_A

Location	Period	AT trend	SL trend	r	S_H	S_A
San Diego	1906–76	0 03 °C yr^{-1}	0.19 cm yr^{-1}	0.67	0.42	~0.04
Los Angeles	1936–75	0.04 °C yr^{-1}	−0.03 cm yr^{-1}	0.74	0.54	~0.03

Values calculated from anomalies of air temperature and sea level after both variables had been de-trended.

For statistical methods see text and ref 13. For trends and variability of yearly mean sea level calculated for various locations, see ref. 14.

It has been customary to adjust sea level data to the effect of the atmospheric pressure (theoretically, at least, sea surface should be depressed by 1 cm for every rise in atmospheric pressure of 1 mbar), however, this is questionable "since variation in atmospheric pressure is associated with change in the direction and velocity of the wind, which is one of the most important factors contributing to the fluctuations in sea level"[7]. The skill index, S_H, calculated between sea level where the 'effect' of the atmospheric pressure has been removed and air temperature at San Diego is 0.37 for the 1929–73 period, which is still higher than the artificial skill of 0.04, and is thus also predictable.

An important question is whether the use of seasonal rather than annual anomalies could improve the correlations presented in Table 1. For example, in several locations in Scandinavia cold winters are often followed by warm summers[15]; so that the annual anomalies of air temperatures might not be representative of the major changes at these locations. However, according to Namias[16], this is not true for the southern California coast. That is, negative or positive seasonal anomalies of air temperatures often persist throughout the year. The average skill index, S_H, between the seasonal anomalies of air temperature and sea level for the San Diego region during 1906–76 period is 0.29 (artificial skill, S_A, is <0.01) which is much smaller than the skill index calculated from the annual anomalies (0.42, Table 1)

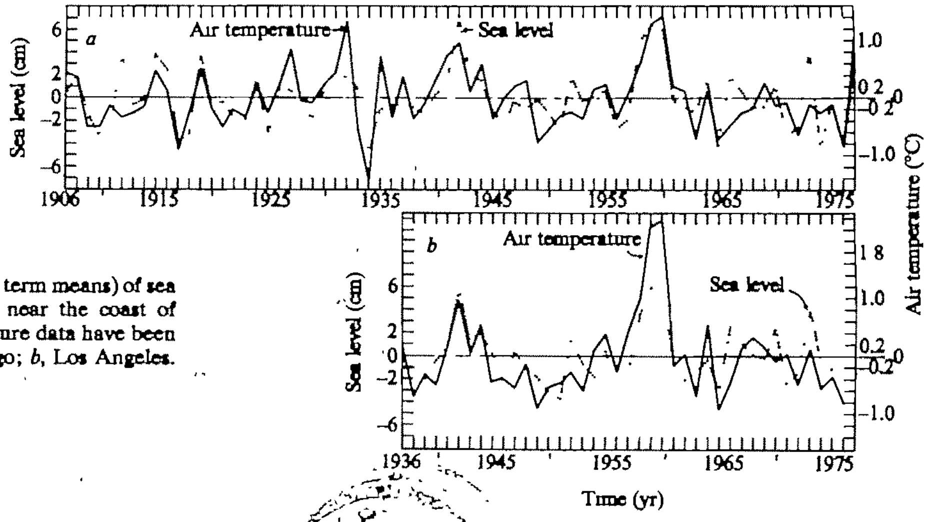

Fig. 1 Yearly anomalies (deviation from long term means) of sea level and air temperatures at two locations near the coast of southern California. Only limited air temperature data have been recorded at Los Angeles Airport. *a*, San Diego; *b*, Los Angeles.

0028-0836/78/0276—0171$01 00

indicating that the use of seasonal anomalies would not improve the correlation.

At best there can only be an indirect cause-effect relationship between air temperature and sea level. However, the remarkable correlations shown in Table 1 strongly suggest that the dominant mechanisms causing fluctuations are the same. Two possible mechanisms for these fluctuations are changes in solar irradiance and wind. Previous research indicates that the most likely mechanism in this case is changes in wind systems.

Reid *et al.*[17] have reported a significant correlation between the monthly anomalies of the northerly wind component and of sea surface temperatures during spring and early summer months. Namias and Huang[11] associated the higher sea surface temperatures and higher sea levels found during 1948–57 as compared to 1958–59 period with a lesser north-to-south wind stress. After an extensive study of current, wind and sea level variations off the Oregon coast Smith[18] reported a high correlation between southwards winds and sea level. Climatological properties of the air characteristic of a location are transported when the wind deviates from its normal flow[19], thus, increased northerly winds are expected to result in lower air temperatures in this region.

This hypothesis may be an oversimplification of the complex meteorological processes which make up climate. However, from a pragmatic point of view, the existence of such a significant correlation between these two variables is of great value to the investigators of various disciplines.

Fossil Holocene seaweed and attached calcareous polychaetes in an anoxic basin, Gulf of Mexico

DURING examination of the planktonic foraminiferal assemblages in a piston-core of black, anoxic sediments (Gyre, 77-G-13, Leg 1, 5-K) of probable early Holocene age from the Orca Basin, northern Gulf of Mexico, we discovered preserved, brown seaweed and calcareous polychaetes from a core depth of 985–1,000 cm. We know of no previous documented case of preserved seaweed in deep-sea sediments, especially with attached organisms, and we describe this material here.

The Orca Basin is a 400 km^2 depression in the continental slope of the northern Gulf of Mexico, which contains anoxic, hypersaline (about 250 g kg^{-1}) water in the bottom 200 m (ref. 1). The salt is considered to be derived by leakage from nearby diapiric structures[1]. Two piston-cores have been taken using the RV Gyre, and we have examined microfossil samples from one of these cores, which consists of black, organic-rich, fetid mud, resulting from the anoxic bottom conditions within this basin. The seaweed fragments are small (<4 mm) and the scanning electron miscroscope shows them to have clear cell walls. The core, located at 26°54′ N, 91°21.5′ W, was raised from a water depth of between 2,400 and 2,450 m and is 12 m in length. The exact depth has not yet been established because sound velocity of the brine in the basin has yet to be determined. As expected, the microfossil sequence preserved in this core is quite atypical for the Gulf of Mexico, consisting of persistent, relatively abundant, and well preserved planktonic foraminifera and radiolaria. Late Quaternary microfossil sequences outside this anoxic basin in the Gulf of Mexico differ from that of the Orca Basin by exhibiting planktonic foraminiferal assemblages that have undergone varying degrees of dissolution; pteropod assemblages occurring only spasmodically and exhibiting conspicuous dissolution and an almost complete absence of radiolarian assemblages[2]. Thus, the unusual sedimentary geochemical conditions within the Orca Basin have created an opportunity to study more complete microfossil sequences than in other areas of the Gulf of Mexico. The sequence contains persistent *Globorotalia menardii* and *Globorotalia tumida* indicating a Holocene age ($t < 10{,}000$ yr BP)[2].

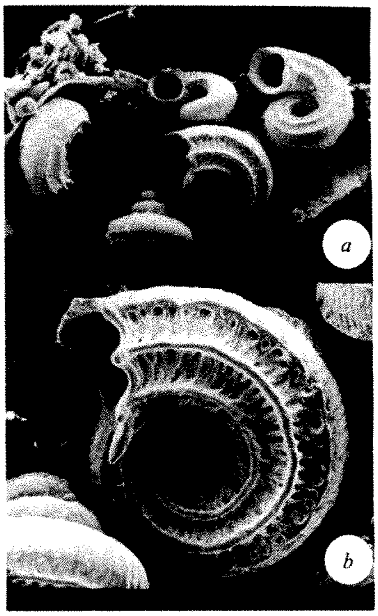

Fig. 1 *a*, Attached dextral specimen of *Janua* sp. on brown seaweed. Specimens are of early Holocene age. (Gyre Core 343, 985–1,000 cm, Orca Basin, northern Gulf of Mexico) ×26. *b*, Higher magnification view of single *Janua* sp. showing details of surface ornamentation of transverse lines and spiral ridges ×63.

We do not know of any previous documentation of seaweed in deep-sea sediments, let alone that with attached fossil organisms. Seaweed is normally very rapidly recycled within the food chain. The attached organisms (Fig. 1*a* and *b*) are calcareous, dextrally coiled polychaetes of the family Spirorbidae. The specimens have been examined (by Richard Beckwitt) and identified as *Janua* sp. based on shell and operculum characters. The specimens (Fig. 1*b*) show conspicuous transverse lines and prominent spiral ridges. The seaweed is a brown form and is probably *Sargassum* which is commonly found floating in warm waters in the Atlantic[3]. Seaweed such as this is apparently commonly deposited in the Orca Basin, as Jeffrey and Schink (personal communication) have discovered a large amount of brown seaweed in a box core from the Orca Basin. It is apparent therefore that the seaweed sank rapidly to the floor of the Orca Basin without being consumed by mid-water organisms, and was preserved in the Holocene sediments because of the anoxic conditions and a lack of benthonic organisms within the basin. Our microfossil examination of the samples revealed an almost

0028–0836/78/0276—0172$01.00

complete absence of benthonic foraminifera and other benthonic microfossils, in contrast to very rich planktonic microfossil sequences (planktonic foraminifera, pteropods and radiolaria) throughout the core. We observed only about four specimens of benthonic foraminifera in the core samples examined. It is unclear whether these specimens somehow managed to live in the Orca Basin or whether they were transported in. The microfossil sequences in the core exhibit no evidence of bottom-sediment transportation. The benthonic foraminifera, however, are so rare they could have been transported in by unusual mechanisms, including seaweed transportation.

We thank Robert Tompkins and Dr David Schink for providing samples from the core. The core was collected by Robert Tompkins. We also thank Richard Beckwitt for his identification of the polychaetes. Donald Scales operated the scanning electron microscope. This research was funded by NSF grant no. OCE75-21262.

Detection of bubbles in decompression sickness

AMATEUR diving and industrial demands have changed decompression sickness from being a specialised problem to becoming a health risk for many thousands of people. Rising medical standards and the recognition of bone damage[1] have resulted in increasingly stringent diving regulations, but the devising of suitable decompression schedules is still largely empirical; our best strategy is still to avoid sickness by accepting grave restrictions on diving procedures (such as decompression for a week or more[2]). It is important to find the earliest events involved, particularly as it is now generally accepted that the condition arises from supersaturated gas separating in the tissues; separation precedes overt symptoms and may remain symptomless[3] and experimentally at least, gas does not readily separate without some nucleus[4,5]. Methods are required applicable to man which can detect separated gas as such, and not by the physiological effect it produces, as early as possible. Various acoustic methods have been used. Bubbles moving in blood vessels have been successfully detected by the Doppler method[6,7] in experiments confirming their significance and presymptomatic existence[3]. However, this method cannot recognise stationary bubbles. We describe here a method using ultrasonic imaging that will make it possible to detect moving or static bubbles down to the required limits, in a chosen plane in the body, and hence to study at the earliest stages the location, development and movement of bubbles in a variety of tissues after subjection to decompression procedures.

The first such method used was an acoustic–optical method[8] which proved lacking in resolution. An alternative, first explored by MacKay[9], uses pulse-echo ultrasonic techniques. The method can, in principle, recognise gas at any site, static or in motion. It should therefore be possible to identify the sites of origin, and analyse the processes of bubble formation. Given this knowledge, one could hope to avoid decompression sickness without the need for tedious (and sometimes damaging) trials.

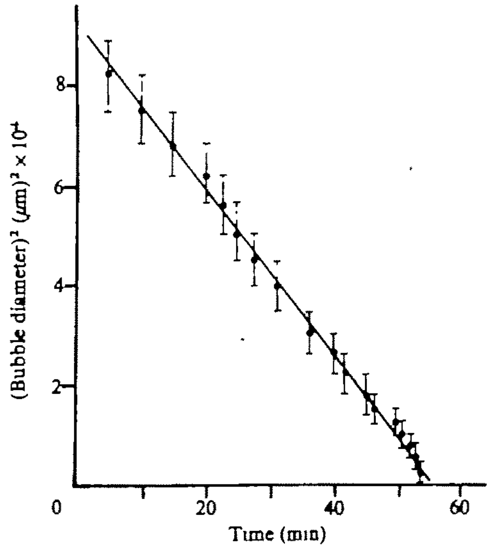

Fig. 1 Plot of bubble decay in degassed water, verifying the Epstein–Plesset equation which relates the square of bubble radius to time. A least-squares linear regression analysis gave a correlation coefficient of 0.998. The error bars represent ±10 μm in measuring bubble diameter.

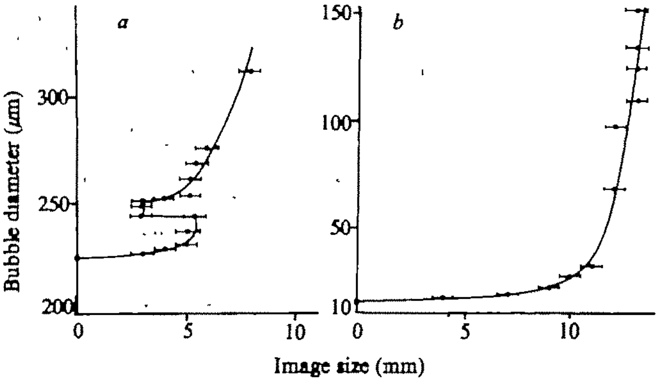
Using a pulse-echo system operating at 7.5 MHz, Rubissow and MacKay[10] reported routine observation of bubbles of 2–5 μm diameter and even down to 0.5 μm in optimum conditions. Furthermore, they suggested that the actual diameter of such bubbles could be measured. The claim that such small bubbles could be detected has been challenged on theoretical grounds but without repeating the experiments[11–13]. At 7.5 MHz the wavelength of sound in tissue is 200 μm and from the relationship between target radius and back-scattered sound intensity[14] this detection limit seemed unlikely. In view of this controversy and the promise of this technique for the study of decompression sickness, an 8-MHz pulse-echo system has been developed: at this frequency, bubbles can be detected down to 10 μm diameter, measured microscopically, but not below; bubble size cannot be obtained from image size for bubbles <300 μm in diameter; and 10 μm diameter bubbles seem likely to be the smallest stable *in vivo*.

The pulse-echo system was based on two commercially available units, which after modification, provided the basic amplitude and brightness modulated displays, with sound frequency 8 MHz and pulse repetition frequency 2 kHz; using a 5-mm

Fig. 2 Ultrasonic image size as a function of gas bubble diameter, plotted by simultaneously observing the decay of the gas bubble ultrasonically and by optical microscopy, *a*, Image size measured using a low (45dB) gain. *b*, Image size measured using a high (80dB) gain. The frequency of sound used was 8 MHz corresponding to a wavelength of 187 μm (the acoustic coupling medium being water).



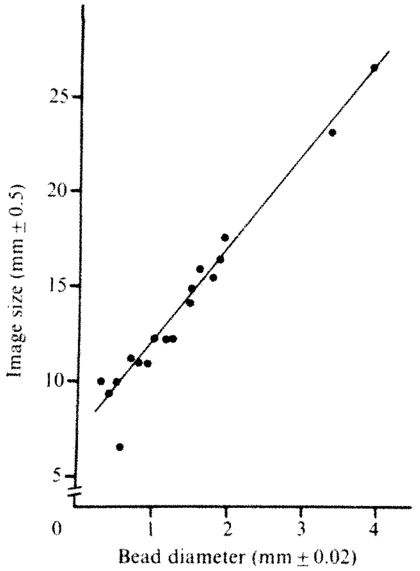


Fig. 3 Ultrasonic image size as a function of target size, measured using spherical glass targets, size range 0.4–3.5 mm diameter. The glass spheres were held in the centre of the ultrasound beam by a fine glass thread. The bead diameters were measured using a microscope fitted with a calibrated graticule. The ultrasonic image sizes were all measured from the photographic record of the images recorded from the glass beads.

diameter probe. The probe is focused with a plano-concave epoxy lens, fixed directly to the face of the PZT-5A transducer. A simple sector scan mode is used, at a frequency of 1 Hz, with the target coupled acoustically to the transducer with water. The ultrasonic images are displayed on a variable persistence oscilloscope. (Full details of the system will be published elsewhere.)

To determine the detection threshold of this system the decay of small gas bubbles in water has been observed simultaneously by the ultrasound system and by optical microscopy, which also allowed the relationship between bubble radius and image size to be determined. The test bubbles were confined in a small depression in a bubble-free block of 4% gelatin, gelatin being both acoustically and optically transparent. The block, held by a hypodermic needle, was positioned in the ultrasound beam with a micromanipulator, and coupled acoustically to the probe by degassed, distilled water. Single bubbles, of ~300 μm diameter, were formed in the cavity using a microelectrode and syringe. Microscopically such bubbles decayed over a period of several hours, and in over 24 h in air-saturated water. Their diameter could be measured to an accuracy of ±5 μm. Bubble decay followed the Epstein–Plesset equation[15], which, ignoring surface tension effects, has the approximate solution:

$$(R/R_0)^2 = 1 - (2x/R_0^2)t,$$

where R = bubble radius; t = time; and x = constant. Although the equation is expected to be inaccurate for small bubbles no appreciable deviation was found in this study (Fig. 1).

The ultrasound images of the bubbles were recorded automatically every 2 s at selected periods during their decay, and continuously when their diameter fell below 50 μm. Under the microscope, when the diameter reached 10 μm the bubbles apparently seemed to vanish suddenly, even in the presence of surfactant, detergent or when the surrounding medium was air saturated. A plot of bubble diameter against image size (Fig. 2) shows that, in optimum conditions (Fig. 2*b*), the detection limit of the ultrasound system is close to 10 μm, but there is no simple relationship (Fig. 2*a*) for bubbles with a diameter <300 μm. This result was expected from consideration of the scattering cross-sections[4,16] when the target radius approximates to the wavelength (at 8 MHz the wavelength of sound in water is 187 μm). In these conditions a variety of complex effects are expected, shown in Fig. 2*a*. Below this critical region (Fig. 2*b*) a monotonic relationship was found but its slope is either too flat or too steep for practical use. However, for bubble diameters >300 μm another simple relationship was indicated and has in fact been supported by experiments with glass spheres (0.3–4 mm diameter) as targets (Fig. 3).

These experiments show that bubbles can be detected down to 10 μm diameter and although larger than previously claimed[10] it seems to be an adequate limit, as no evidence was found microscopically for free bubbles smaller than this. Bubble size can be obtained from image size, for bubbles of diameter >300 μm, but below this a complex situation exists where an increase in bubble size may lead to a decrease in image size. One consequence is that bubble sizes cannot be calculated by applying small pressure changes and interpolating bubble size by observing the change in image size and applying Boyle's law. This technique has been used previously[10] and would lead to erroneous conclusions. Preliminary experiments have shown that the method is capable of detecting both fixed and moving gas bubbles in the legs of decompressed, anaesthetised guinea pigs.

Somatic polymorphism and seed dispersal

SOMATIC seed polymorphism is the production of seeds of different morphologies or behaviour on different parts of the same plant and is a somatic differentiation rather than the result of genetic segregation[1]. This phenomenon appears to be confined to a limited number of families of higher plants (for example, Cruciferae, Compositae, Chenopodiaceae, Gramineae). Seed produced within a somatic polymorphism may vary in size (*Xanthium* sp.[2]), colour (*Atriplex heterosperma* Bunge[3]) and/or external structure (*Chenopodium album* L.[4]). These variations in morphology are frequently accompanied by differences in germination requirements with the consequence that the germination of polymorphic seeds may be staggered in time. Such somatic channelling of progeny into distinct classes of behaviour may increase the fitness of individuals in environments that are temporally patchy, at the expense of the intrinsic rate of increase that could be attained by a unique seed type in a

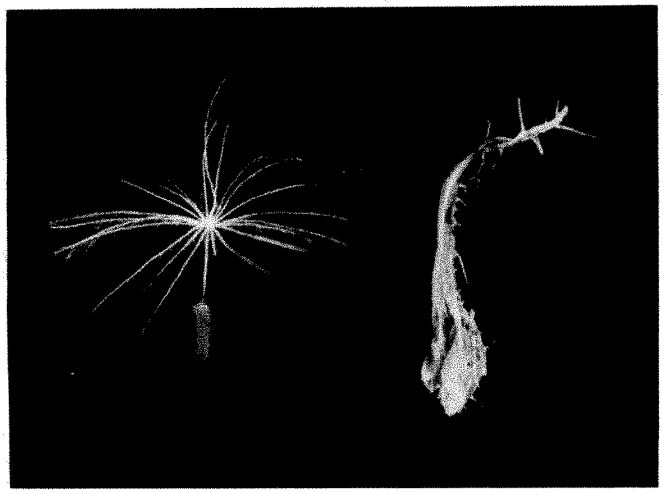
0028-0836/78/0276—0174$01.00

uniform environment. It might be expected that somatic seed polymorphism would also be found in species occupying habitats that are patchy in space and under these circumstances polymorphism in dispersal mechanisms could also be anticipated. One reported case may come in this category; *Gymnarrhena micracantha* Desf.[5], a desert annual, produces numerous small aerial wind-dispersed achenes (the fruit in Compositae is usually termed an achene but is strictly a pseudo-nut as the pericarp is partly axial and there is more than one carpel[6]) and also larger subterranean achenes close to the parent plant. The wind dispersed achenes are produced in greater numbers in years with high rainfall. The subterranean achenes serve only to establish descendants in the safe sites previously occupied by their parents. We report here an even more striking polymorphic dispersal mechanism in the biennial *Picris echioides* L. (Compositae).

P. echioides (bristly ox-tongue) is a fugitive species associated with woodland and wayside clearings. The plants grow to about 50 cm tall and the stems and leaves are covered with numerous bristles. Yellow flower heads are surrounded by an involucre of leafy hairy bracts. Flowers within the capitula are ligulate, the majority producing rufous achenes, transversely wrinkled towards the short beak which bears a pappus of 20 white silky hairs. However, each of the larger marginal outer achenes is tightly held in an enclosing involucral bract; these achenes are covered with short white hairs and have a shorter beak and shorter, vestigial pappus hairs (Fig. 1). Inner achenes weigh about 0.015 g and the dissected embryo weighs 0.005 g. Outer achenes weigh about 0.029 g and the embryo 0.010 g. There are approximately 25 inner and six outer achenes per involucre. The inner achenes are clearly wind dispersed, although the pappus and beak readily break off during or after dispersal. The outer achenes remain within their bracts when the inflorescence falls as a whole. The bracts are hairy and sharply bent, suggestive of animal dispersed propagules.

Three hundred pappus-bearing inner and 300 bract-enclosed outer achenes were scattered randomly on the floor of a 90 cm × 60 cm plastic enclosure. Two laboratory mice (*Mus musculus*) were released in the container for 35 min; the number of seeds transported, the seed retention time and the behaviour of the mice were recorded. In a further experiment a laboratory mouse was placed in a straw-lined 120 cm × 60 cm enclosure, fed on a diet of laboratory pellets and seeds of *Festuca rubra* and allowed to habituate for 7 d, during which time the mouse established a nest. Two hundred and fifty inner achenes and 250 outer achenes (in bracts on senesced flowerheads) were scattered randomly within the enclosure. The transport of achenes to the nest by the mouse was recorded daily. The outer achenes stuck to the forefeet, hindfeet and tail base of the mice in the first experiment; several outer achenes were carried for up to 195 s (Fig. 2). The adhered achenes did not appear to irritate the mice, nor did they seem to be attractive as a food source. In a few cases the mice actively removed the seeds by chewing but the majority of achenes dropped off passively. No inner achenes were ever observed to adhere to a mouse. A daily count of seeds in the second experiment showed that there was a continued transport of senesced flowerheads (containing outer achenes) to the established nest of the mouse. Again no inner achenes were ever transported in this manner.

Fig. 1 Achenes of *Picris echioides*. Left, inner pappus-bearing achene; right, outer achene enclosed in involucral bract.



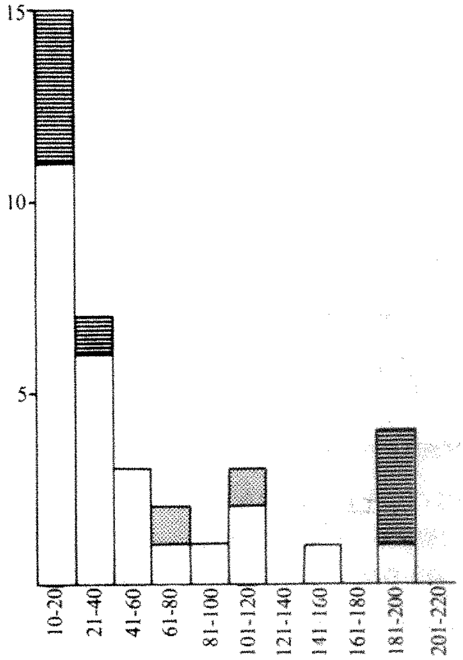


Fig. 2 Frequency distribution of the time for which the outer (bract-enclosed) achenes of *Picris echioides* remained attached to laboratory mice. No inner (pappus-bearing) achenes were ever observed to adhere to the mice. ▤, Attached to tail; □, attached to forefoot; ▩, attached to hindfoot.

The transport of whole capitula implied active caching or the removal of attached flowerheads through grooming at the nest site. The disinterest of mice in outer achenes as a food source in the first experiment and the high chaff to embryo ratio of outer achenes, which must reduce their digestive value, suggests that caching is unlikely. Instead the accumulation of outer achenes in the nest appears to be due to passive transport followed by grooming.

It might be expected that the two types of achene, which differ in size, would have different dormancies, rates of seedling growth or competitive ability (particularly when grown in mixed populations[7]). A series of experiments revealed no such differences[8]. It appears therefore that the achene dimorphism in *Picris echioides* may be related simply to differences in dispersal behaviour. In nature, potential animal dispersers of *P. echioides* include *Clethrionomys glareolus*, *Microtus agrestis*, *Micromys minicticus* and *Apodemus sylvaticus*. The behavioural patterns and nesting habits of these small mammals may well effect transport of the seeds of *P. echioides* into habitats quite different from those that would be reached by wind dispersal.

Somatic seed polymorphism results in the production of a constant ratio of seed types regardless of short term 'patchiness' of the environment and prevents 'tracking' of transient changes. This phenomenon contrasts with the genetic polymorphism of seed dispersal mechanisms such as that found in *Aegilops speltoides* Tausch[9] in which two kinds of dispersal unit are borne, but on different individuals. Such genetic polymorphism is sensitive to changing direction and intensities of selection, hence the observed fixation of monomorphic populations on the fringes of the distribution area of *A. speltoides*. In contrast, somatic polymorphisms as in *P. echioides*, are buffered against rapid response to selection; all individual plants are monomorphic and every individual appears to bear polymorphic achenes.

Cell sorter analysis of leukaemia-associated antigens on human myeloid precursors

NORMAL and malignant B cells, some monocytes and blast cells from both the common (non-T, non-B) form of acute lymphoblastic leukaemia (ALL) and acute myeloblastic leukaemia (AML) share Ia-like antigenic determinants[1-4]. ALL cells, but not AML cells, can be further characterised by the expression of an 'ALL-associated' membrane antigen[9,10]. Although the ALL antigen and the Ia-like antigens on leukaemic blasts have at one time been regarded as candidate leukaemia-specific antigens, it has been suggested that both may be normal differentiation antigens of haematopoietic precursors, their expression in leukaemia reflecting the cellular origins of the disease[2,7-11]. In immunofluorescent studies combined with phase contrast examination, Ia-like antigens can be demonstrated on normal and leukaemic myeloblasts and some promyelocytes, but not on most promyelocytes and maturing granulocytic or erythroid cells[7,8]. The presence of Ia-like antigens on myeloid-committed stem cells is supported indirectly by results of functional assays *in vitro* which show the abolition of myeloid colony-forming cells (CFUc) by incubation with complement and hetero-antisera to B cells[12,13]. Two disadvantages of the approach used in the latter experiments are, first, that the cells of interest are eliminated and no longer available for analysis, and second, that their functional inhibition does not necessarily establish that they carry the antigens in question, as the development of colonies involves stimulatory factors[14,15] and auxiliary cells, whose activity, rather than CFUc *per se*, might be compromised by the antibodies used. We now report direct evidence for the presence of the antigens on bone marrow cells by separating them in a fluorescence-activated cell sorter (FACS), according to their binding of anti-Ia-like (anti-p28,33) or anti-ALL antibodies. Functional analysis of the resultant populations reveals that a proportion of human colony and cluster forming cells express the Ia-like hetero-antigen but not the ALL-associated antigen.

Table 2 Morphology of separated Ia$^+$ and Ia$^-$ bone marrow cells

	Adult bone marrow Unsorted	Adult bone marrow Ia$^+$	Adult bone marrow Ia$^-$	Fetal bone marrow Unsorted	Fetal bone marrow Ia$^+$	Fetal bone marrow Ia$^-$
Blast cells	2.5	35.5	2	13	33*	8
Promyelocytes	1	32.5	2	7	10	8
Myelocytes	30	12.5	42	17	2	18
Maturing granulocytic cells	29.5	6	21	11	3	30
Monocytes	7.5	3	3	3	3	4
Red cell precursors	16	2	20	9	0	10
Lymphocytes	13	7.5	10	31	36	14

Cells were prepared as described in Table 1 and separated on FACS. Smears were made and stained with May–Grünwald–Giemsa. Differential counts are shown as percentages.

*Most cells are myeloblasts. Some resemble lymphoblasts.

For convenience, we refer below to the anti-p28,33 sera as anti-Ia and to the cells bearing the p28,33 determinants as Ia$^+$. This terminology presumes more than is proven of the genes involved in the control of these molecules in man; however, the human B cell p28,33 complex has strong structural similarities to rodent Ia molecules[4,16,17]. The 33K component in man is apparently regulated by genes on chromosome 6 (ref. 18) and carries the polymorphic determinants which are identified by human anti-(HLA) *D* locus sera[19,20]. The membrane antigens specifically reactive with anti-p28,33 on leukaemic blasts are, as on B cells, associated with a noncovalently bonded p28,33 complex[21]. The anti-ALL antibodies used here, although produced by immunisation with whole cells, selectively bind to a single glycosylated polypeptide species with an apparent molecular weight of 100,000 (ref. 22). Reactive cells are referred to as ALL$^+$.

After elimination of most mature granulocytic and erythroid cells by Ficoll–Triosil density centrifugation, adult marrow samples contained 10–14% cells reactive with anti-Ia serum (Table 1). Ia$^+$ cells included larger cells, mainly myeloblasts

Table 1 Characterisation of Ia$^+$ cells in human bone marrow with membrane markers

Source of bone marrow	Adult (61 yr)			Fetus (19 weeks)			Regenerating (6 yr) (off treatment for ALL)		
	Total*	Small*	Large*	Total	Small	Large	Total	Small	Large
Cells reacting with:									
Normal rabbit serum	<1			<1			<1		
Anti-Ia-like serum (Ia$^+$)	14	4	10	48	30	18	32	20	12
Anti-ALL serum (ALL)$^+$	<1			13	12†	1	14	14†	0
Anti-Ig (SmIg$^+$)	5	4	1	10	10†	0	10	9†	1

To eliminate red cells, normoblasts and granulocytes, cells were separated on Ficoll–Triosil and treated with 0.17 M NH_4Cl for 15 min. The cells were then passed through fetal calf serum and washed The antisera used were ultracentrifuged before use (100,000*g* for 1 h). Cells were incubated for 20 min at 4 °C with either normal rabbit serum (NRS 1 10 dilution) or rabbit anti–Ia serum made against purified human p28,33 Ia-like antigens (Ia; 1:20 dilution)[4,5,8] or rabbit anti-ALL serum (ALL; 1:10 dilution)[9,21], washed three times, incubated for 20 min with fluoresceinated goat anti-rabbit immunoglobulin (1:50 dilution) and washed three times again Other samples were incubated with goat anti-human immunoglobulin directly labelled with fluorescein or rhodamine-isothiocyanate (anti-Ig-FITC or anti-Ig-TRITC))1:10 dilution) and washed three times The samples shown were analysed by the FACS (see Fig. 1). Adult bone marrow samples were obtained from ribs removed during operation for lung cancer. Patients were 55–65 yr old. Fetal bone marrow samples were from 19–21-week-old fetuses. Representative experiments are shown. Regenerating marrow samples were obtained from children after the completion of chemotherapy regimes given for the treatment of acute lymphoblastic leukaemia. The bone marrow sample shown was taken from a 6-yr-old child who had been off treatment for 8 months. The marrow showed moderate lymphocytosis. The analysis was carried out 7 months ago and the child is still in complete remission of his leukaemia.

*% of cells showing positive membrane staining under UV microscope

†Double marker experiments (anti-ALL: FITC; anti-Ig: TRITC) showed that ALL$^+$ cells were SmIg$^-$, and SmIg$^+$ cells were ALL$^-$ (ref. 11). Ia$^+$ lymphocytes failed to form rosettes with sheep erythrocytes and did not react with anti-thymocyte serum[22].

3*e* Sorted Ia$^-$ cells	20.1 ± 5.7	17.3(52.7%)	19.1 ± 0.8	9.9(9.5%)	413.3 ± 81.4	281.0(81.0%)
Calculated totals after sorting		32.8(100%)		104.0(100%)		347.0(100%)

Preparation of cell suspensions is shown in Table 1. Histograms of the stained cell suspensions were made on the FACS (Fig. 1) and Ia$^+$ large and small cells and Ia$^-$ cells were separated. Cells in each fraction were counted, plated in double-layer agar cultures[15] and incubated for 7 d. In all experiments, changes in numbers of colonies (>40 cells per clone) corresponded with changes in clusters (<40 cells per clone). In addition, no difference was detected in the proportion of compact (granulocytic) and diffuse (macrophages + mixed) colonies. NT, not tested. *a*, Observed values expressed as numbers (±s.d.) of colonies and clusters (that is, clone-forming cells) per 10^4 cells plated. *b*, Calculated numbers of Ia$^+$ and Ia$^-$ clone-forming cells in 10^4 cells of the original cell population. The formula is: value *a* × proportion of Ia$^+$ or Ia$^-$ cells (from Table 1). The sum of Ia$^+$ and Ia$^-$ *b* values shows the total number of clone-forming cells per 10^4 cells recovered after sorting. If this is taken as an arbitrary 100%, then the relative contribution of Ia$^+$ and Ia$^-$ cells can be given (in parenthesis).

*These cells were passed through the FACS but were not sorted.

and promyelocytes (Table 2), and smaller SmIg$^+$ (surface membrane-immunoglobulin-positive) B lymphocytes. The Ia$^-$ cells were myelocytes, maturing granulocytic and erythroid cells, a few lymphocytes and <5% myeloblasts and promyelocytes.

In normal fetal bone marrow and regenerating juvenile marrow, more cells (30–50%) reacted with anti-Ia serum than in adult marrow (Fig. 1*b,c*, Table 1). Again, the Ia$^+$ cells included large lymphoblasts, myeloblasts and promyelocytes as well as small lymphocytes. The latter were heterogeneous by membrane marker criteria: 8–15% were B lymphocytes (SmIg$^+$, ALL$^-$) and the remaining lymphocytes reacted weakly with anti-ALL serum (ALL$^+$), were negative for SmIg (SmIg$^-$) and failed to form rosettes with sheep erythrocytes or to react with anti-thymocyte serum. These non-T,non-B ALL$^+$ cells are not readily detectable in the adult marrow samples[9,11]. As in the adult marrow, the Ia$^-$ cells in fetal and regenerating marrows were mainly maturing granulocytic and erythroid cells; however, Ia$^-$ myeloblasts were also seen (Table 2).

The data obtained in the myeloid clonal assays are shown in Table 3. The binding of anti-Ia antibodies to bone marrow cells in the absence of complement (Table 3, line 3*a*) and manipulations with the cells on the FACS (Table 3, line 2, last column) neither inhibited nor significantly stimulated clone-forming cells. A striking finding was that colony and cluster-forming cells were present in both Ia$^+$ and Ia$^-$ fractions. Accumulation of these clone-forming cells in the Ia$^+$ fraction (Table 3, line 3*b*) with concomitant depletion in the Ia$^-$ fraction (Table 3, line 3*e*) was observed in five of seven experiments. Note, however, that in the Ia$^+$ fractions invariably fewer cells were observed than in the Ia$^-$ fractions (Table 1). When the total contribution of the different cell populations to the colony and cluster-forming cells was calculated in the different experiments, the Ia$^+$ cells contained 10–80% of clone-forming cells (mean 40%, seven experiments). Representative values are shown in Table 3. The remaining clone-forming cells (mean 60%) were sorted into the Ia$^-$ fractions. The wide diversity of Ia expression on clone-forming cells was confirmed when adult marrow cells were separated into strongly Ia$^+$, moderately Ia$^+$ and Ia$^-$ fractions. Colony and cluster-forming cells were observed in all three populations (Table 4). Mixed and pure neutrophil–granulocyte and macrophage clones and pure eosinophil clusters (8–14%) were found in cultures of all fractions.

Clone-forming cells were found almost exclusively among the intermediate-to-large cells (Table 3, line 3*d*), suggesting that small Ia$^+$, ALL$^+$ non-T,non-B cells did not form myeloid colonies. This notion was directly confirmed. Fetal marrow cells were stained with anti-ALL serum, separated on the FACS and cultured for 7 d. The ALL$^+$ and ALL$^-$ fractions gave, respectively, 3.2 and 626 clones per 10^4 cells.

We interpret these results to suggest that a proportion of human myeloid precursors are Ia$^+$ and a few of them are very

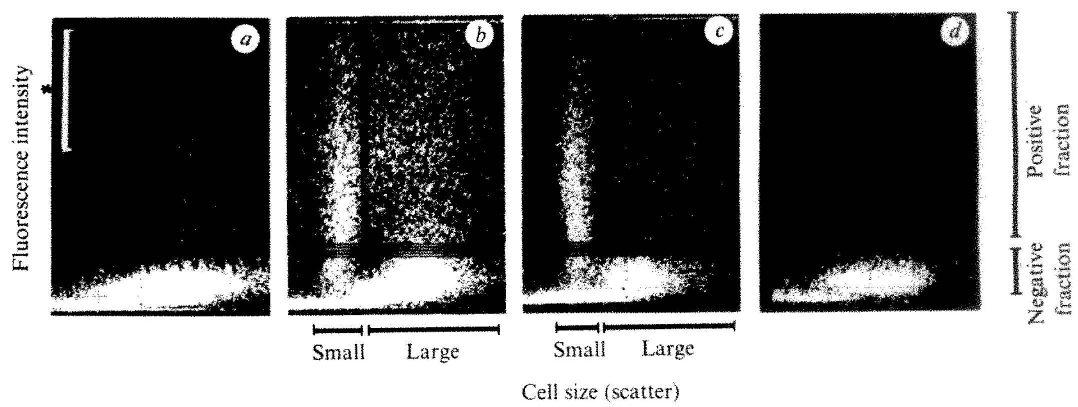

Fig. 1 Bone marrow cells were stained with anti-Ia serum (*a–c*) or normal rabbit serum (*d*, negative control) as described in Table 1. Histograms made on the FACS-1 (Becton Dickinson) are shown. The cells were separated on the basis of fluorescence intensity (Ia$^+$ compared with Ia$^-$ fractions). Ia positivity was arbitrarily defined as staining intensity above negative controls (*d*). The nonspecific staining in suspensions incubated with NRS was checked on the UV microscope in each experiment and found to be minimal. Some samples were also separated on the basis of cell size (small against large) as indicated. The cells within the shaded areas were discarded. The standard conditions of FACS setting were: laser power 400 mW at 488 nm; scatter channel gain 2; fluorescence channel gain 8; photomultiplier tube 700 V (see footnote to Table 4). In these conditions the proportions of Ia$^+$ and Ia$^-$ cells detected on the FACS agreed with the observations made on the UV microscope (Table 1). *a*, Adult; *b*, fetal; *c*, regenerating.

Table 4 Colony and cluster-forming cells express a wide range of Ia densities on the cell membrane

Strong Ia$^+$	581 ± 172*
Moderately Ia$^+$	449 ± 24
Ia$^-$	217 ± 44
Unseparated	277 ± 57

Normal adult bone marrow cells were stained with anti-Ia serum and separated into strongly Ia$^+$, moderately Ia$^+$ and Ia$^-$ fractions on the FACS and cultured (clones per 10^4 cells plated ± s.d.).

*Intensity of fluorescent staining is shown in Fig. 1*a* by an asterisk.

strongly Ia$^+$. As very weakly Ia$^+$ cells might have been sorted into the Ia$^-$ fraction in the conditions used on the FACS, our results do not exclude that a larger proportion of clone-forming cells carry Ia-like antigens when analysed by other techniques, for example, by complement-mediated cytolysis. Nevertheless, our data indicate a striking heterogeneity of Ia expression on myeloid precursors which could not be appropriately documented with other techniques. The results also strongly suggest that small cells of lymphoid morphology with the antigenic phenotype of acute lymphoblastic leukaemia (ALL$^+$, Ia$^+$) are not CFUc. This fact has not been unequivocally established, as ALL$^+$ cells might require the collaboration of large Ia$^+$ cells for their development into colonies. This possibility seems unlikely, however, as in our experiments the separated cells were cultured on peripheral blood feeder layers which provided an ample source of colony-stimulating factors[23].

These findings suggest that the two distinct Ia$^+$ non-T,non-B cell types (that is, the smaller ALL$^+$ cell and the larger ALL$^-$ cell which express some myeloid characteristics) might represent the target cells for leukaemic transformation in the common (non-T,non-B) form of ALL and in AML respectively. This implies that leukaemic blasts largely retain at least some of the antigenic characteristics of cells from which they are derived[11]. Alternatively, the target cell in ALL and AML could be an even less mature haematopoietic stem cell, subsequent maturation of the leukaemic clones being 'frozen' at the level corresponding to the two cell types. The nature of the ALL$^+$, Ia$^+$ 'lymphoid' cells is unknown; we regard these cells as candidate lymphocyte precursors or stem cells[11].

These and previous studies[7,8,24,25] indicate a maturation-linked expression of Ia-like antigens with a progressive loss during granulocyte differentiation. Whether the striking variability of Ia-like antigen expression on CFUc cells is related to particular stages of cell differentiation, governed by events linked to the DNA synthetic cell cycle[25,26] or due to other factors is essentially unknown and warrants further study.

We thank Mr J. R. Belcher, Dr N. Rapson, Dr S. Lawler and the Tissue Bank of Royal Marsden Hospital, for bone marrow samples. Mr D. Delia and Ms J. Berney gave technical help. The study was supported by the ICRF (G.J., M.F.G., D.C.) and the Wellcome Trust (G.F.).

Novel form of T-cell stimulation of immunoglobulin secretion

THE precise mechanism of action by which helper T cells induce precursor B cells to acquire the capacity to secrete immunoglobulins[1,2] remains poorly understood. This paucity of information is due, in part, to the temporal lag between the initial T cell–B cell interactions relatively early in the process and the subsequent expression of these interactions a day or more later[3,4]. This time lag presumably relates to the time required for B cells to undergo a maturation or differentiation after interaction with T cells. We now report that, using a pulse-label technique, we have observed that the addition of thymus cells to previously cultured spleen populations during the 90-min pulse-label period resulted in a marked increase in the rate of secretion of immunoglobulin. Moreover, the enhancement occurred without detectable delay.

Unimmunised New Zealand white rabbits were used as a source of lymphoid tissue. The method for preparing cell

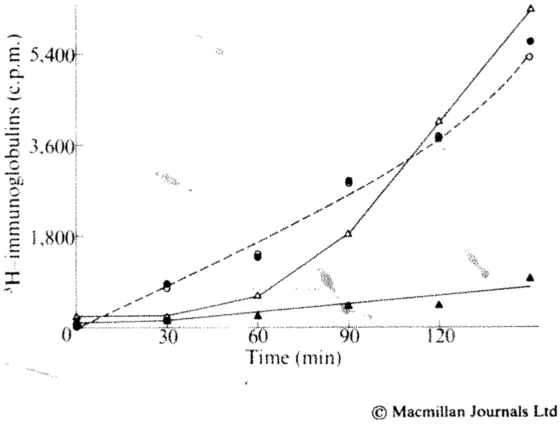

Fig. 1 Effect of thymocytes on the rate of appearance of intracellular and extracellular ^{3}H-immunoglobulin. The procedure is described in the legend to Table 1. Spleen cells were cultured for 72 h before use and thymocytes were isolated on the day of use. ▲, △, Extracellular fluid; ●, ○, intracellular fluid. Open symbols, both splenocytes and thymocytes; closed symbols, splenocytes only.

0028–0836/78/0276—0178$01.00

suspensions[5] and the procedure used for tissue culture were as previously described[6,7]. Assessment of immunoglobulin production by coprecipitation analysis[8] and the preparation and specificity characteristics of anti-thymocyte serum has also been described[7,9]. Spleen cells were centrifuged on a Ficoll gradient and those cells concentrated atop the 30% layer were used in cell culture[10].

The effect of mixing separately cultured splenocytes and thymocytes is shown in Table 1. Although freshly isolated spleen cells failed to exhibit increased ^{3}H-immunoglobulin secretion on addition of thymocytes (experiment 1), spleen and thymus cells, cultured separately for 2 or 3 days before being mixed at the beginning of the 90-min pulse-label period, yielded increased ^{3}H-immunoglobulin secretion above that observed with spleen alone.

From the results of experiment 1 it was not clear whether both thymus and spleen cells required a prior culture period before being mixed in the pulse-label assay. Accordingly, an experiment was performed in which the duration of prior incubation for each cell type was varied. It can be seen (Table 1, experiment 2) that it was necessary to culture spleen cells for at least 2 days and preferably for 3 days in order to observe the rapid onset effect of thymus cells. In contrast, prior incubation of thymus cells was not required and, indeed, tended to reduce the extent of stimulation that was ordinarily observed with fresh thymus cells.

Table 1 Effect of mixing separately cultured splenocytes and thymocytes

Expt no.	Cells present during pulse-label period	Length of prior incubation of: spleen	thymus	^{3}H-immunoglobulin secreted during pulse-label period
		(d)	(d)	(c.p.m.)
1	Spleen	0	NA*	60
	Spleen + thymus	0	0	40
	Spleen	1	NA	90
	Spleen + thymus	1	1	80
	Spleen	2	NA	360
	Spleen + thymus	2	2	680
	Spleen	3	NA	720
	Spleen + thymus	3	3	2,570
2	Spleen	3	NA	230
	Spleen + thymus	3	3	1,530
	Spleen + thymus	3	2	3,450
	Spleen + thymus	3	1	3,210
	Spleen + thymus	3	0	4.970
	Spleen	2	NA	90
	Spleen + thymus	2	3	200
	Spleen + thymus	2	2	360
	Spleen + thymus	2	1	510
	Spleen + thymus	2	0	750
	Spleen	1	NA	50
	Spleen + thymus	1	3	60
	Spleen + thymus	1	2	80
	Spleen + thymus	1	1	70
	Spleen + thymus	1	0	100

Spleen and thymus cells were separately cultured in Medium 199 containing 10% fetal calf serum for the indicated number of days. After being washed with leucine-free medium 199, spleen cells (10^{7}) with or without thymus cells (6×10^{7}) were incubated in the presence of such medium containing ^{3}H-leucine for 90 min at 37 °C. At the end of this period, the ^{3}H-immunoglobulins secreted into the extracellular fluids were assessed by coprecipitation of one aliquot in the presence of carrier rabbit immunoglobulin and goat anti-rabbit immunoglobulin and another aliquot in the presence of egg albumin and goat anti-egg albumin. The difference in these samples reflects specifically precipitable rabbit immunoglobulins. The values shown for mixtures of spleen and thymus have been corrected for the small amounts of ^{3}H-immunoglobulin detected when thymus cells were incubated alone. This correction corresponded to 1% of the ^{3}H-immunoglobulins found when spleen and thymus cells were incubated together.

* NA, not applicable.

Table 2 Evidence for T-cell participation in enhancement of secretion of immunoglobulin

Cells added to spleen cells	^{3}H-immunoglobulin secreted
	(c.p.m.)
None	530
Thymus	2,200
Thymus (ATS*-treated)	740
None	400
T-cells (nylon wool)	2,300
Thymus	2,600

The procedure is described in the legend to Table 1. Spleen cells were cultured for 72 h before use, whereas the thymus cells used were freshly isolated. Spleen T-cell enriched populations were prepared on nylon wool columns[13] using freshly isolated cells.

* ATS, antithymocyte serum.

Analysis of the effect of thymocytes on the rate of appearance of intra- and extracellular ^{3}H-immunoglobulins revealed that the rate of appearance of intracellular ^{3}H-immunoglobulins within spleen cells was essentially unaltered by the presence of thymus cells, whereas thymocytes markedly enhanced the rate of appearance of extracellular immunoglobulin (Fig. 1). However, meaningful comparison of the rate of appearance of intracellular and extracellular immunoglobulins may not be possible because intracellular ^{3}H-immunoglobulins are composed not only of molecules destined for secretion but also of molecules that are sequestered, for example, surface immunoglobulins. Furthermore, since the proportion of cells containing intracellular ^{3}H-immunoglobulins which respond to thymus cells is not known, the curves for the intra- and extracellular appearance of ^{3}H-immunoglobulins may not be directly related.

In other experiments using shorter time intervals, the initial thymocyte-induced enhancement of ^{3}H-immunoglobulin secretion was detectable at 20 min (data not shown). The precise time of onset of enhanced ^{3}H-immunoglobulin secretion due to thymocytes cannot be closely defined for a period earlier than 15–20 min because lymphoid cells exhibit a secretory lag of approximately 15 min[11,12] during which little or none of the readily detectable intracellular ^{3}H-immunoglobulins can be observed extracellularly. Considered in this context there was essentially no delay in the onset of enhanced secretion due to thymus cells.

The effect of thymocytes was specific in that the rate of extracellular appearance of ^{3}H-labelled serum albumin from liver cells was not enhanced when liver cells were incubated in the presence of thymus cells. Evidence consistent with the view that T cells participate in the rapid onset enhancement of immunoglobulin secretion is shown in Table 2. Thus, the stimulation by thymocytes was lost by prior treatment with antithymocyte serum and complement. In addition, freshly isolated splenic T-cell enriched populations[13] were as efficacious as thymocytes.

Of the ^{3}H-immunoglobulins secreted in response to thymus cells approximately 65% were accountable for as IgM and 35% as IgA by specific coprecipitation analysis. In contrast, ^{3}H-immunoglobulins of the IgG class were not detected. The foregoing experiments have been performed using spleen cells cultured in the absence of added antigen and the resulting immunoglobulin secretion measured by a pulse-label assay. Recently, we have been able to detect the same rapid onset enhancement due to thymus cells using spleen cells cultured with sheep red blood cells (RBC) as antigen and a plaque assay for sheep RBC.

It will be of considerable interest to determine whether the secretagogue-like activity of thymocytes induces a substantial change in B cells or a subtle change. For example, does the alteration require the assembly or reinforcement of most of the cells' total secretory apparatus or does it simply alter the rate of release of completed molecules awaiting discharge at some terminal compartment very close to the end of the intracellular translocation process?

Absence of H–Y antigen in XY females with dysgenetic gonads

WITH a few exceptions[1–6], the mammalian testis is known to differentiate in the presence of a Y chromosome[7], but the mechanism(s) involved remains unknown. Increasing experimental evidence shows that the testis-determining gene product is a plasma membrane protein known as H–Y antigen[8]. Several investigators have demonstrated that the gene(s) controlling H–Y antigen expression are located on the Y chromosome[9,10]. We now report the absence of H–Y antigen in 46 XY pure gonadal dysgenesis (PGD) in which patients have female internal and external genitalia and 'streak' gonads.

We studied nine subjects (20–38 yr old), three normal males, three normal females and three phenotypic females with primary amenorrhoea. Before treatment the three patients had the limb proportions of eunuchs, and had no breast development or axillary hair, although a few coarse hairs were present on the labia majora. There were no signs of Turner's syndrome. These three patients could therefore be categorised under PGD. Two of them were siblings.

Cytological studies using fluorescent and G-banding techniques on all the three patients confirmed their 46 XY karyotype (Table 1). H–Y antigen was assayed immunologically by the cytotoxicity test[11] (Fig. 1). We found that cells from PGD, like those from normal females, did not express H–Y antigen.

There are reports of the familial occurrence of this condition consistent with X-linked inheritance[12]. The locus responsible could be the same as that involved in the XY female wood lemmings[13].

Table 1 Cytological status of nine subjects

Diagnosis	Age range (yr)	X chromatin	Y chromatin	Karyotype from blood	No. of metaphase plates scored
Normal male					
($n = 3$)	25–35	–	+	46 XY	75
Normal female					
($n = 3$)	25–38	+	–	46 XX	65
PGD					
S.M.	28	–	+	46 XY	70
N.B.	36	–	+	46 XY	75
P.B.	20	–	+	46 XY	70

N.B. and P.B. are sibs.

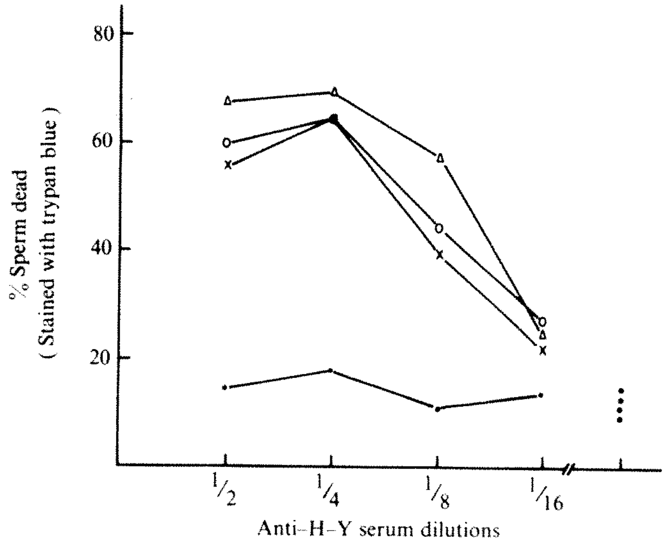

Fig. 1 Cytotoxicity test on mouse sperm with mouse H–Y antiserum after absorption with lymphocytes from three patients with PGD, three normal males and three normal females. Control (C) includes complement but no H–Y antiserum. Each point represents an average value for three separate tests. H–Y antisera were raised in C57 BL/6 female mice by five weekly intraperitoneal injections of spleen cells (4.5×10^6) from C57 BL/6 male mice. Absorption was accomplished by suspending a fixed number of lymphocytes (10^7 cells ml^{-1}) in small tubes containing 0.15 ml of H–Y antiserum diluted one half, and by leaving the suspension for 40 min on ice. Suspensions were agitated gently every 10 min. After absorption, the tubes were centrifuged into aliquots for use in the cytotoxicity test. Cytotoxicity was demonstrated with C57 BL/6 epididymal sperm according to the method of Goldberg *et al.*[11]. Equal volumes (0.05 ml) of H–Y antiserum (serially diluted 1/2 to 1/16), sperm (5×10^6 ml^{-1}) and absorbed rabbit serum (complement source diluted 1/4) were incubated at 37 °C for 50 min. Trypan blue dye (0.1 ml) was added during the last 10 min of incubation to stain dead sperm, and cells were counted in a haemacytometer. The failure of loss of cytotoxicity after absorption with female and PGD cells indicates that these cells do not contain H–T antigen. △, Unabsorbed antiserum; ○, absorbed, female; ×, absorbed, PGD; ●, absorbed, male.

There are three possible explanations of our observations as well as those from XY female wood lemmings: (1) inhibition of the testis-determining gene on the Y chromosome by abnormal gene(s) carried either on the X chromosome or on an autosome(s)[14]; (2) a mutation at the H–Y locus of the Y chromosome probably inactivating the gene product so that its essential function(s) is affected; (3) an X-linked Y suppressor gene that blocks the expression of the H–Y antigen[15]. Whatever the mechanism, it is certain that in the absence of H–Y antigen, as in our cases of PGD, the gonad could not be differentiated into testis. Since Mullerian duct derivatives such as uterus, fallopian tubes and vagina are present in all our patients, it is highly probable that blocking of the expression of H–Y antigen has occurred before initiation of gonadal differentiation.

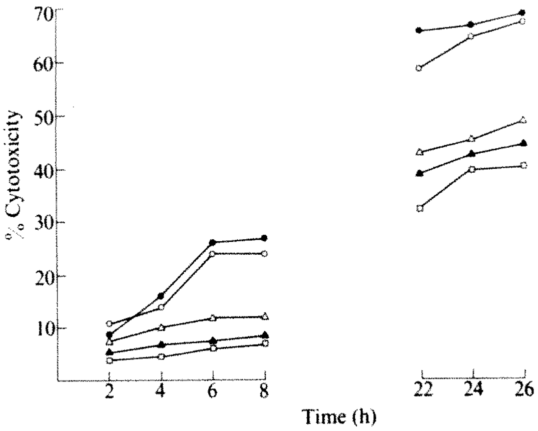
H-2 restriction and non-restriction of T-cell-mediated cytotoxicity against mouse mammary tumour targets

CELL-MEDIATED CYTOTOXICITY (CMC) against C3H/Umc (C3H) syngeneic mammary tumours measured *in vitro*, after *in vivo* immunisation, is mediated by cytotoxic T lymphocytes (CTL) and is directed mostly against cross-reacting antigens related to the mouse mammary tumour virus (MTV)$^{1-3}$. The long-term CMC assay required for detecting this response against adherent target cells has complex kinetics and at least two superimposing components: (1) an initial early peak of cytotoxicity, detectable at approximately 6 h and accounting for 20–30% of the CMC, and (2) a later peak, detectable after 18–20 h and representing an additional 40–50% of the cytotoxic effect^3. Both peaks are mediated by CTL with the Ly23 phenotype (that is, Ly1$^-$Ly2,3$^+$); however, non-cytotoxic T cells of Ly1 and probably Ly123 phenotype (that is, Ly1$^+$Ly2,3$^-$ and Ly1$^+$Ly2,3$^+$, see refs 3 and 4 for nomenclature and functional characteristics of these T-cell subsets) are required for the expression of the second cytotoxic peak^3. On the other hand, the short-term assays of CTL-mediated CMC show single-hit kinetics^5, perhaps comparable to part of the early CMC peak in our system. During our studies of immunity to syngeneic mammary tumours, we observed that when C3H or C3Hf immune CTL were tested against allogeneic MTV-induced mammary tumour targets, a relative degree of H-2 restriction of CMC was observed^2, although not of the magnitude detected in other systems using mostly short-term CMC assays$^{6-11}$. The experiments reported here show that when the kinetics of the CMC response against adherent syngeneic and allogeneic mammary tumour targets were compared, some differences became apparent: whereas the early CMC peak showed absolute H-2 restriction, no restriction was observed in the late CMC peak, although both events were mediated by Ly23 CTL (ref. 3).

Fig. 1 Cell-mediated cytotoxicity (CMC) of lymph node (LN) cells from C3Hf mice (C3H/Umc foster-nursed on C57Bl females, see ref. 1 for details) immunised with C3H/Umc (C3H) mammary tumour cells against syngeneic and allogeneic mammary tumour target cells, shows absolute H-2 restriction of the early CMC peak (2–8 h) and relative H-2 restriction of the late CMC peak (22–26 h). All tumours induced by the mouse mammary tumour virus (M-MTV) have appeared spontaneously and are kept *in vitro* using techniques described in ref. 1. Tumours tested were: C3H/Umc (MT.1 used for immunisation), C3H/HeJ (both have the *H-2 kk* haplotype similar to the LN cell donors), A/J (*H-2 kd*), RIII (*H-2 rr*) and (I × C57Bl/6)F$_1$ (*H-2 jj/bb*). The immune C3Hf LN cells were obtained from mice immunised by temporary growth in the footpad of a C3H/Umc mammary tumour (MT.1), followed by amputation 15–20 d later and collection of the regional LN 7–9 d after amputation^3. Immune LN cells were tested for CMC using ^{3}H-proline-pre-labelled adherent target cells (1,000 cells per well of microtest plates II, Falcon Plastics) and 100:1 effector:target ratios. The mixtures were incubated for the indicated times at 37 °C in humidified 5% CO$_2$ in air and the per cent cytotoxicity calculated as described in ref. 3 in relation to the target cells incubated with non-immune C3Hf LN cells (based on the measurement of the remaining adherent target cells per well after washing in experimental and control groups). For further details on cell preparation, target labelling and recovery of labelled adherent cells, see ref. 3. ●, C3H; ○, C3H/He; △, A; ▲, RIII; □, (I × C57BL/6)F$_1$.



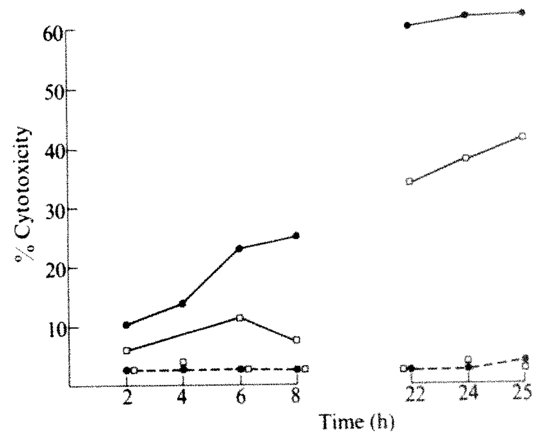


Fig. 2 Abrogation of early and late CMC of specifically immune C3Hf LN cells against syngeneic and allogeneic mammary tumour targets, by pretreatment of the effector LN cells with anti-Ly-2.1 and rabbit complement (C). Ly2 is an antigen expressed on T cells^{3,4}. For details on the CMC assay using ^{3}H-proline-labelled adherent target cells, *in vivo* immunisation and *in vitro* treatment of effector cells with anti-Ly sera, see ref. 3. Treatment with anti-Thy-1.2 and C also produced abrogation of both CMC peaks (data not shown, see also ref. 1). Conversely, removal of B cells by pretreatment with rabbit anti-mouse Ig and C had no effect on CMC; thus, at 24 h CMC was 59% in the syngeneic and 40% in the allogeneic target. Similarly, the addition of rabbit anti-mouse Ig (or control rabbit serum) at concentrations of 100 and 200 μg of Ig per culture had no effect on the early or late CMC peaks on the syngeneic or allogeneic target (data not shown). The addition of heat-aggregated goat IgG (at a concentration of 50 or 100 μg per ml of culture media) also had no effect on the early or late CMC peaks (data not shown). These additional studies confirm the view that both CMC peaks on syngeneic or allogeneic targets are mediated by T-effector cells. ●, C3H; □, (I × C57BL/6)F$_1$; —, control; - - -, anti-Ly-2.1 + C.

The early CMC peaks (2–8 h, Fig. 1) produced by C3Hf immune CTL against syngeneic C3H or H-2-identical (C3H/He) targets were comparable, whereas CMC was markedly reduced against the allogeneic targets. The late peak (22–26 h, Fig. 1) also seemed to show some degree of H-2 restriction^2. Figure 2 shows comparable data for the CMC response against C3H and (I × C57B1/6)F$_1$ targets during the early and late peaks, but also includes the abrogation of such responses by pretreatment of the CTL with Ly-2.1 serum and C, confirming our previous observation that both CMC peaks are mediated exclusively by Ly23 CTL (ref. 3). Figure 3 shows that when the whole time course of the response of C3Hf CTL against syngeneic or allogeneic mammary tumour targets was measured, it was evident that the late peak, appearing at 18 h, was quite comparable in magnitude and kinetics between the allogeneic and syngeneic targets. Thus, the relative H-2 restriction observed in the late peak in Fig. 1 was due to the absence of the early H-2-restricted CMC peak. It can be concluded that although the early CMC peak in the present model system shows absolute H-2 restriction, no such restriction is observed for the late CMC peak.

0028-0836/78/0276—0181$01.00

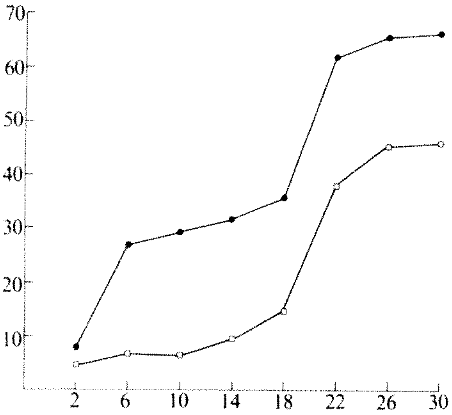

Fig. 3 Time course of CMC of C3Hf specifically immune LN cells against syngeneic (●) and allogeneic ((I × C57BL/6)F_1, ☐) mammary tumour target cells, showing absolute H–2 restriction of the early CMC peak (2–18 h) and no H–2 restriction of the late CMC peak (22–30 h), as the shape and magnitude of the late curve are comparable for the syngeneic and allogeneic targets. The difference in total CMC at 30 h between the allogeneic and syngeneic targets which appears as relative H–2 restriction is due to the absence of the early CMC peak in the allogeneic combination. For details on immunisation and assay system see Fig. 1 and ref. 3.

The interpretation of the present results requires some definitions concerning the assay and the system[3] in relation to the H–2 restriction model[6–8]. CTL generated *in vivo* in the local lymph node after hyperstimulation (temporary syngeneic tumour growth and removal) show specific *in vitro* CMC directed against syngeneic (or allogeneic) mammary tumour targets that requires relatively long-term assays for detection[1–3]. The kinetics of this assay indicate that complex events operate in the generation of the CMC response and that non-cytotoxic helper or amplifier T cells are required for the expression of maximal CMC[3]. Based on the timing of the response it is probable that the second peak of activity represents tertiary stimulation of memory cells into CTL, as observed in syngeneic and allogeneic systems[12,13], whereas the initial peak may represent CMC comparable to the short-term assays in other systems, and a possible measure of conventional CTL activity[5].

If this sketchy interpretation is accepted, several hypotheses may explain the observed non-restriction of the late peak. (1) Ly1 helper cells. As Ly1 helper–amplifier cells are required for the generation of the non-restricted second peak[3], it is possible that specific Ly1 help against the H–2–MTV complex in the allogeneic targets is generated during the long-term assay and that such help can by-pass the H–2-restricted activity of the Ly23 CTL. (2) Memory is non-restricted. Most of the literature on responses to viral and other antigens does not support this hypothesis[12–17]. In general, syngeneic cells bearing the appropriate antigen can induce good levels of CTL regeneration in secondary or tertiary stimulation[12–14], although H–2 identity may not be an absolute requirement[15–16]. However, it is accepted that the pattern of CMC of secondary cells is similar to that of the primary CTL[12–17]. (3) Changes in avidity of CTL. In allogeneic systems, it has been shown that avidity of CTL is influenced by time and antigen dose, in terms of antigen-driven selection of pre-cytotoxic T-cell clones with a spectrum of affinities for antigen[18]. Thus, cells with high-affinity receptors would be stimulated preferentially by antigen, giving rise early in the response to a low number of CTL with high affinity (and susceptible to H–2 restriction?). Later, cells with lower affinity would be stimulated, especially when the amount of antigen is not limiting, generating CTL with less avidity (and perhaps without H–2 restriction). Some of the kinetic data of the allogeneic responses fit well with the timing described in our assay for the generation of the second CMC peak[18], the putatively less avid, non-H–2-restricted tertiary CTL response. (4) Genetics of restriction. Cross-reactive lysis of hapten-modified targets has been observed when certain mouse strain combinations are tested[19]. One possible explanation of our data could be that secondary or tertiary activation of CTL in our system may show cross-reactive lysis (perhaps also under genetic control).

Several other explanations may account for the observed differences. These could include: (1) intrinsic properties of the assays (that is, most of the H–2 restriction has been shown with short-term assays, and in fact, no restriction was observed when longer assays were used[15,20–23]; (2) properties of the adherent mammary tumour lines or changes in H–2 expression during the assay (an inverse relationship between expression of MTV antigens and D-end specificities of H–2 has been observed[1]); (3) part of the CMC in our system is not mediated by T cells (this point has been eliminated by the experiments described in Fig. 2); (4) our system belongs to a non-restricted category[20–23]. Experiments to decide between some of these interpretations are in progress.

Complete protection from low-dose streptozotocin-induced diabetes in mice

STREPTOZOTOCIN (SZ) is a broad-spectrum antibiotic with oncolytic, oncogenic and diabetogenic properties[1–4]. To produce diabetes in experimental animals, SZ is administered as a single bolus, injected either intravenously (i.v.) or intraperitoneally (i.p.). Within 72 h, selective destruction of pancreatic beta cells and hyperglycaemia occur[3,5]. Subdiabetogenic doses of SZ cause only mild degranulation of the β-cells without hyperglycaemia during the first 72 h, unlike multiple (five) subdiabetogenic (i.v. or i.p.) doses of SZ to Charles River Laboratory (CD-1) mice, which produce marked glucose elevations within 5–6 days of the last injection of SZ, associated with morphological evidence of insulitis[6,7]. To dissociate direct β-cell toxicity of SZ from the delayed appearance of the insulitis and hyperglycaemia, we used antilymphocyte serum and 3-*O*-methyl-D-glucose (3-OMG), a nonmetabolised glucose analogue, which prevents the occurrence of hyperglycaemia for at

0028-0836/78/0276—0182$01.00

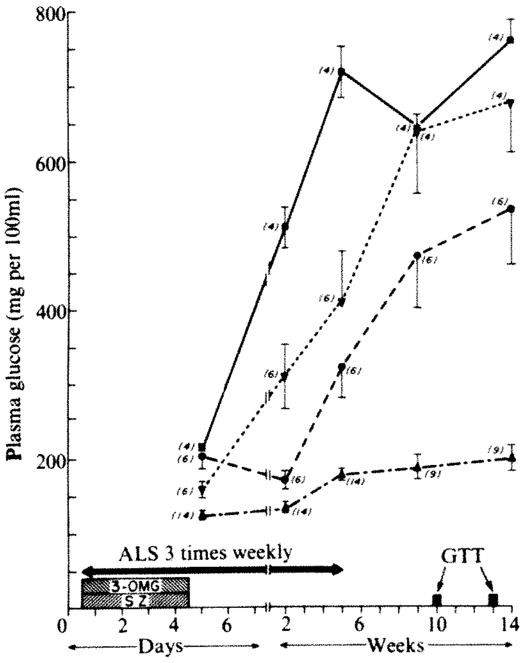
least 72 h, when administered to mice or rats prior to a single diabetogenic dose of SZ[8,9]. Antilymphocyte serum (ALS), while not altering the multiple subdiabetogenic SZ-induced hyperglycaemia, does protect against the lymphocytic infiltration of the pancreatic islets, without changing the delayed hyperglycaemic response observed following the combination of 3-OMG and SZ injections[10]. We report here that injections of ALS (for 5 weeks), in combination with a regimen of 3-OMG and SZ, prevented the development of hyperglycaemia for the entire 14 weeks of the experiment, and that mice demonstrated essentially normal intraperitoneal glucose tolerance tests and pancreatic histology during the 3rd and 4th months following SZ.

Four groups of mice were studied. Group 1 ($n = 4$) received five daily i.p. injections of SZ (40 mg per kg body weight). Group 2 ($n = 6$) received five daily injections of SZ and, in addition, i.p. ALS, 0.25 ml three times daily for a total of 5 weeks, including the period when SZ was administered. Group 3 ($n = 6$) received i.p. 3-OMG (1g per kg) before each of the five SZ injections. Group 4 ($n = 14$) received the combination of 3-OMG plus SZ and ALS.

Figure 1 represents the results of plasma glucose (PG) determinations. Mice receiving multiple injections of SZ alone (Group 1) showed an increase in plasma glucose (PG) by the second week. Mice injected with the combination of SZ and ALS (Group 2) had lower PG concentrations during the period of ALS administration, afterwards increasing to levels comparable to the group that received SZ alone. The group that received 3-OMG plus SZ (Group 3) showed no increase in PG for approximately 2 weeks, then PG rose to a level slightly lower than that observed in animals that received SZ alone or SZ plus ALS. In marked contrast to these three groups, the mice injected with the combination of SZ, 3-OMG and ALS (Group 4) remained normoglycaemic for the entire 14 weeks of the experiment.

Glucose tolerance tests for Group 4 were not significantly different from those of the normal controls (Fig. 2). Histological examination (9th week ($n = 5$) and the 14th week ($n = 9$)) of the pancreatic islets revealed subtle architectural disarray, occasional foci of infiltrating mononuclear cells, and mild β-cell degranulation at both time intervals. Islets from Group 4 did not show the marked lymphocytic infiltration or β-cell destruction observed previously in mice receiving SZ alone[6,7].

Fig. 1 Plasma glucose levels (mean ± s.e.m.) for 14 weeks in CD-1 mice after: five daily i.p. injections of SZ (40 mg per kg) (■); ALS injections (0.25 ml) three times per week for 5 weeks plus SZ (▼); 3-OMG (1 g per kg) before each SZ dose (●); 3-OMG, plus SZ plus ALS regimen (▲). Numbers in parentheses indicate the number of mice in each group. The mice, histological examination, collection, and assaying glucose levels, preparation and administration of 3-OMG, SZ, and ALS, are as previously described[10]. GTT, i.p. glucose tolerance test.



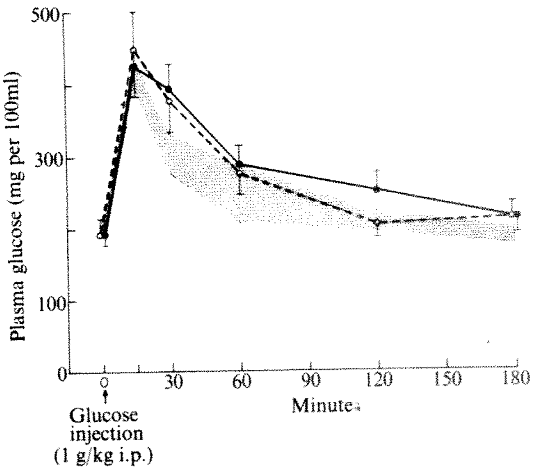


Fig. 2 I.p. glucose tolerance test. Plasma glucose response following i.p. injection of glucose (1 g per kg) in a volume of 1 ml, in animals which received the combination of 3-OMG, SZ and five weeks of ALS. The tests on experimental animals were performed during the 10th week and 13th week of the experiment. Also shown are the plasma glucose levels of five normal mice given i.p. glucose (1 g per kg) (stippled line). Numbers in parentheses indicate the number of mice in each group. ○, At 10 weeks ($n = 9$); ●, at 13 weeks ($n = 9$).

A plausible explanation of the protection provided by 3-OMG against the β-cell toxicity of SZ is that of direct competition between 3-OMG and SZ for a surface receptor site on the β cell[9]. In mice, a single injection of 3-OMG (2 g per kg) prior to SZ (up to a dose of 180 mg per kg) prevents β-cell necrosis and diabetes for up to 72 h[8]. The quantity of 3-OMG used in the present experiments should provide complete protection against each of the five injections of SZ (40 mg per kg). However, as previously observed[6], the administration of 3-OMG (1 g per kg) immediately before each of five consecutive daily doses of SZ (40 mg per kg) provided protection against glucose elevations for only approximately 2 weeks, after which the animals became diabetic, which correlated with the presence of insulitis[10]. We suggest that either 3-OMG is unable to protect the β cell completely from direct SZ toxicity, or that SZ initiates a response which is only partially affected by 3-OMG preinjection.

SZ-treated animals were given ALS to see if insulitis and/or hyperglycaemia could be attenuated by prolonged immunosuppression. In previous experiments, ALS administered for 10 consecutive days (that is, during the five daily injections of SZ, plus 5 days thereafter) produced no appreciable diminution in plasma glucose levels when compared with animals receiving SZ alone, However, the ALS-treated mice showed no insulitis and the combination of 3-OMG, SZ and ALS (10 injections) did not provide additional protective effect beyond that attributable to the five daily doses of 3-OMG alone[10]. The occurrence of diabetes in the ALS-treated animals might be considered paradoxical if our hypothesis of an immunological basis for the multidose SZ diabetes syndrome is correct unless the immunosuppression by ALS was inadequate to prevent the delayed β-cell destruction.

In the present study and in others using the inbred C57BL/KsJ mouse ($n = 10$) (data not shown), more prolonged administration of ALS (5 weeks) prevented diabetes. One explanation is that in the mice treated with ALS for only 10 days, the autoimmune state capable of destroying the β cells, was only temporarily suppressed by the ALS treatment. In contrast, the prolonged injection of ALS for five weeks suppressed the autoimmune state to a greater extent, islet (β cell) injury was minimised and physiological impairment of glucose tolerance did not occur during the 14 weeks of the experiment.

If direct β-cell toxicity by SZ is not the only mechanism by which the animals eventually became diabetic, the protection afforded by ALS at any time would be difficult to explain. We can assume that ALS must have protected the mice against the destructive effects of the postulated cell-mediated immune reactions against the β cell. The immunosuppressive mechanism of β-cell destruction remains to be elucidated.

SZ-induced diabetes can be ameliorated by simultaneous administration of 3-OMG and prolonged administration of ALS. We suggest that 3-OMG reduces the direct β cytotoxicity of SZ, and permits the antilymphocyte effects of ALS to be expressed by inhibiting the inflammatory islet lesions and the diabetic syndrome. Our results strengthen the hypothesis that cell-mediated autoimmunity plays a role in the pathogenesis in the model of SZ-induced insulitis.

Sulphonylureas increase the number of insulin receptors

SULPHONYLUREA drugs have been widely used in the management of the form of diabetes mellitus which develops in adulthood. Although some endogenous insulin secretory capacity seems to be necessary for sulphonylureas to be effective (they are ineffective in pancreatectomised animals), their precise mechanism of action has not been clear. Short-term administration of sulphonylureas to animals or humans is associated with increased insulin secretion[1,2]. However, prolonged administration reduces pancreatic insulin content in animals[3,4] and diminished insulin secretion in reponse to nutrient stimulation in both laboratory animals[5] and humans with adult-onset (insulin-independent) diabetes[6,7]. Treatment with sulphonylureas also decreases the biosynthesis of proinsulin[8]. Thus, the chronic antidiabetic action of sulphonylureas does not seem to result from an effect on insulin release, but rather from one or more extrapancreatic effects[9,10]. In that connection, we have shown that chronic administration of the sulphonylurea, glipizide, to patients with adult-onset diabetes mellitus results in significant potentiation of insulin action, as assessed by changes in insulin-mediated glucose disposal[11]. On the basis of those results, we have suggested that glipizide influences the interaction of insulin with the cell membranes in insulin-sensitive tissues. We now report that, in an animal model, such an effect involves an increase in the number of insulin receptors.

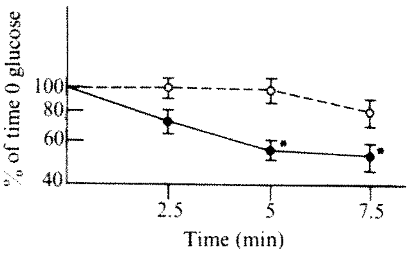

Fig. 1 Potentiation of insulin action by glipizide treatment in normal mice. 15–20-g male mice were treated with diet + glipizide (5 mg per kg per d) or diet alone for 10 d. Following a 5-h fast, the mice were injected intravenously with 2.5 mU pork insulin and killed at the specified times for measurement of plasma glucose. Each data point is the mean ± s.e. of five observations. The data are expressed as % of plasma glucose at time 0. Insulin had no effect on the plasma glucose in the control mice, but caused significant hypoglycaemia in the glipizide-treated mice at 5 and 7.5 min. ○, Control; ●, glipizide; * $P < 0.05$.

Male Dublin strain mice (15–20 g) were fed measured amounts of a standard diet. Glipizide (5 mg per kg per d) was added to the diet of half of them for 10 d. Weight and content of glucose and insulin in the plasma during fasting were not significantly different in controls and in mice receiving glipizide. However, sensitivity to insulin was enhanced by glipizide (Fig. 1); 2.5 mU of pork insulin did not significantly alter the plasma glucose of controls, but significant hypoglycaemia occurred in glipizide-treated mice 5 min after administration of insulin. Moreover, the concentration of insulin in the plasma at each of the times shown in Table 1 demonstrates that glipizide had no effect on insulin degradation and that insulin action was potentiated at physiological insulin concentrations. Thus, treatment of normal mice with glipizide potentiated the action of insulin on glucose disposal in a similar manner to that demonstrated in humans with diabetes mellitus.

We next investigated whether this potentiation of insulin action was accompanied by a change in the characteristics of insulin binding to the membranes of insulin-sensitive tissue. A second group of mice was given a standard diet with or without glipizide. After 10 d the livers were removed and homogenised, and purified plasma membranes were isolated by ultracentrifugation on a 15–55% linear sucrose gradient. Fractions

Table 1 Plasma insulin in mice following an intravenous dose of 2.5 mU of regular insulin

Time (min)	Glipizide treatment (μU ml^{-1})	Control (μU ml^{-1})
0	<2.5	<2.5
2.5	27.3 ± 4.2	30.5 ± 6.8

containing plasma membranes were identified by measurement of 5′ nucleotidase activity[12], and those containing endoplasmic reticulum were identified by measurement of NADH oxidase activity[13]. Protein concentrations were determined by the method of Lowry[14]. The specific activity of 5′ nucleotidase in the pooled plasma membrane fractions was 15 times that in the crude homogenate. Enzyme profiles and specific activities were identical for the livers of all mice. Insulin binding to plasma membranes was determined by incubation of membranes for 15 h at 4°C with biologically active ^{125}I-insulin and various concentrations of unlabelled insulin[15].

Figure 2 shows a representative experiment comparing (by Scatchard analysis[16]) insulin binding to purified hepatic plasma membranes from a glipizide-treated mouse with binding from a control mouse. The shapes of the two curves are similar, indicating that glipizide did not alter affinity for insulin. In contrast, the liver membranes of the treated mouse bound twice as much insulin as those of the control. ^{125}I-growth-hormone binding was assessed in the same way, using samples of liver membrane from the preparations already used for insulin binding. There was no difference between control and glipizide-treated mice in growth-hormone binding or displacement.

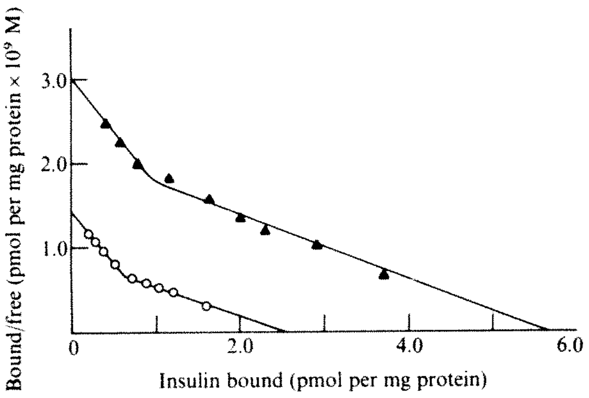

Fig. 2 Scatchard plot of insulin binding by purified hepatic plasma membranes from a glipizide-treated mouse and a control mouse. Binding studies were done by the method of Kahn *et al.*[15]. ○, Control; ▲, glipizide.

Table 2 summarises data calculated from four experiments similar to that depicted in Fig. 2. The Scatchard plots are curvilinear, including either negative cooperativity, binding sites of different affinities, or both. To facilitate analysis, we assumed that the first part of the curve represented a high-affinity binding site and the second part a low-affinity site. However, our conclusions do not depend on a choice between alternative mechanisms for curvilinearity. There is no significant difference in the affinity constant (K_a) between the control and glipizide-treated mice for either the high or low affinity receptors, but glipizide-treated animals have more than twice as many receptors.

Our findings provide a basis for understanding the effects of glipizide on patients with adult-onset diabetes mellitus. These patients have a marked resistance to insulin action[17], which is probably a primary defect. Although the mechanism involved has not been elucidated, abnormally low numbers of insulin receptors have been found in such insulin-resistant states as adult-onset diabetes[18] and obesity[19]. Olefsky and Reaven reported that when plasma glucose was decreased by treatment with sulphonylurea in a group of adult-onset diabetic patients, the number of insulin receptors on their circulating monocytes increased[18]. Our observation that successful treatment with glipizide is associated with a potentiation of insulin action on glucose disposal[11] is consistent with a glipizide-induced increase in the number of available insulin receptors on the plasma membranes of responsive tissues. Our data suggest that this effect is not secondary to a decrease in plasma glucose.

Table 2 Effect of glipizide treatment on purified hepatic plasma membrane insulin receptors

	High affinity receptor		Low affinity receptor	
Treatment	Receptor no. (pmol per mg)	K_a (10^9 m^{-1})	Receptor no. (pmol per mg)	K_a (10^9 m^{-1})
None	1.4 ± 0.1	1.0 ± 0.2	2.1 ± 0.1	0.4 ± 0.1
Glipizide (5 mg per kg per d)	3.2 ± 0.6*	0.9 ± 0.2	4.6 ± 1.0*	0.4 ± 0.1

Data are mean ± s.e. of four separate experiments.
* $P < 0.05$.

Our results suggest that *in vivo* glipizide treatment increases the number of insulin receptors on the target cell membrane, enhancing sensitivity to insulin[20]. The number of plasma membrane insulin receptors *in vivo* is influenced by many factors, and our data do not enable us to delineate the precise way in which glipizide acts. Possibilities under study include direct effects on the plasma membrane, an increase in target cell cyclic AMP, which might increase the number of insulin receptors[21], or an alteration in the mechanism by which insulin modifies the characteristics of its own receptor.

Although our results represent an important step towards understanding the mechanism of action of sulphonylurea drugs, their clinical value can be determined only by analysis of epidemiological studies comparing long-term benefits and risks. We do not know whether sulphonylureas increase insulin receptors and insulin sensitivity in all patients with adult-onset diabetes or in only a subset of patients, and the duration of the effect is unknown. Our data do, however, have practical importance in guiding the development of new drugs which influence membrane function and insulin action and in amplifying the concept of insulin resistance as a major metabolic defect in adult-onset diabetes mellitus.

Tolerance of locus coeruleus neurones to morphine and suppression of withdrawal response by clonidine

NORADRENERGIC neurones of the locus coeruleus (LC; A6 of ref. 1) are inhibited by the systemic or local administration of adrenergic agonists[2-5], opiates[6,7] and enkephalins[8,9]. The adrenergic receptors of the LC, which are of the presynaptic or α_2 type[5], seem to mediate inhibitory responses to recurrent LC collaterals[10] and adrenaline inputs from the lower brain stem[4,11]. In addition to adrenergic receptors, there are opiate receptors located in the LC[12,13] which presumably mediate the actions of endogenous opiate-like substances (enkephalins and β-endorphin) located in nerve terminals within the LC[14-16]. Recently, clonidine, which is the most powerful of the α_2 agonists known to inhibit the firing of LC neurones[3,5], has been reported to suppress the symptoms of opiate withdrawal in humans[17]. On this basis, the latter authors suggested that the opiate-withdrawal syndrome may be due in part to increased noradrenergic neuronal activity in areas such as the LC which are regulated by both α_2 adrenoceptors and opiate receptors. In this connection, it is interesting that the drug piperoxane, which blocks α_2 adrenoceptors and accelerates the firing of LC neurones[4,5] produces many of the symptoms (such as anxiety and hypertension) seen in opiate withdrawal[18]. In the present study, single-cell recording and microiontophoretic techniques were used to establish the development of tolerance of LC cells to the depressant effects of morphine, naloxone-induced withdrawal activations of LC neuronal firing in morphine-dependent animals, and the ability of clonidine to suppress the withdrawal of LC neurones through a non-opiate receptor.

Thirty male albino rats (Charles River) weighing 225–275 g were used. The animals were anaesthetised with chloral hydrate (400 mg per kg, intraperitoneally) and mounted in a stereotaxic instrument. Morphine tolerance and dependence were induced by the method of subcutaneous pellet implantation[19,20]. The pellets, which contained 75 mg of morphine base, were implanted daily for 1–5 d. For the single LC-cell recordings, a burr hole was made 1.2 mm posterior to lambda and 1.1 mm lateral to the midline. As described previously[2-6,10], practical aids in finding the LC include: (1) depth 5.5–6.5 mm below dural surface; (2) a zone of relative electrical silence ventral to the cerebellum and dorsal to the LC corresponding to the fourth ventricle; (3) the presence just lateral to the LC of cells of the mesencephalic nucleus of the fifth nerve, which are activated by displacement of the mandible; (4) in the LC itself, a closely packed population of slowly firing cells all responding to noxious stimulation by a burst of firing followed by a long quiescent period (~1 s). Ultimately, the recording sites were marked at the end of each experiment by iontophoretically ejected dye (Pontamine sky blue) for histological confirmation of LC and other recording sites.

Procedures for single-cell recording and microiontophoresis were as described previously[5]. The 5-barrel micropipettes which were used were broken to a tip size of 3–5 μm; impedances of the recording (central) barrels were 3.5–5.5 MΩ (filled with 2 mM NaCl containing 2% Pontamine sky blue). Solutions for microiontophoresis were as follows: morphine sulphate, 0.1 M, *p*H 4 (Merck); piperoxane, 0.1 M *p*H 4 (Rhone-Poulenc); clonidine HCl, 0.01 M in 0.1 M NaCl, *p*H 4 (Boehringer-Ingelheim); naloxone HCl, 0.05 M, *p*H 4 (Endo). Note that, because of its extreme potency in inhibiting LC neurones, the clonidine was ionically diluted with NaCl to reduce its transport number[3]. A retaining current of −10 nA was applied to all drug barrels between periods of ejection. Per cent inhibition was determined by the average rate for the 1-min period immediately following iontophoretic ejection; baseline rate was taken from the 1-min period just before ejection.

The firing of LC neurones slowed gradually and became totally suppressed within 1–2 h of implantation of a single morphine pellet (*n* = 4 animals); activity remained suppressed for about 24 h, and returned towards normal rates by 48–72 h. This pattern is consistent with the fact that morphine is released most rapidly from implanted pellets within the first 24 h[19,20]. LC cells could be activated by a noxious stimulus during periods of morphine inhibition, as has been reported previously[6]. Twenty-four hours after the last of 4–5 daily pellet implantations, the firing of randomly encountered LC neurones (mean rate 1.2 spikes s^{-1}, *n* = 20 cells) was nearly as high as in control animals (mean rate 1.4 spikes s^{-1}, *n* = 20 cells). The difference between LC firing rates in chronic morphine-treated and control animals was not statistically significant ($P > 0.1$, Student's *t* test), indicating that the morphine pellet implantation procedure had induced a considerable degree of tolerance. In control animals, the microiontophoretic application of morphine at a low ejection current (+5 nA) produced marked inhibitory effects (87% mean depression, *n* = 10 cells) on LC neurones; at low ejection currents naloxone totally blocked these effects of morphine but did not increase baseline firing rates (Fig. 1*a*).

At a low ejection current (+5 nA) clonidine caused a similar degree of depression in LC cell firing (91% mean depression, *n* = 10 cells) despite the fact that the effect of morphine had been totally blocked by the concurrent microiontophoresis of naloxone (Fig. 1*a*). Conversely, the α antagonist piperoxane blocked the effect of clonidine without altering the response to morphine

Fig. 1 The effects of microiontophoretically applied morphine and clonidine on the firing of LC neurones in control and morphine-dependent rats. In *a*, taken from a recording in a control animal, the initial marked inhibitory effect of morphine (MOR) was totally blocked by naloxone; clonidine (CLON) had its usual inhibitory effect even in the presence of naloxone. In *b*, also taken from a control animal, piperoxane (PIP) selectively blocked the inhibition produced by clonidine; the response to morphine after piperoxane was virtually identical to the original response. In *c*, taken from a morphine-dependent animal (24 h after five consecutive daily pellet implantations), the initial inhibition produced by morphine was only about 50%; an activation of firing was induced by naloxone iontophoresis, during which time the inhibitory effect of morphine but not clonidine was blocked. The records represent average rate histograms generated by the analog output of an electronic counter (10 s reset time). Periods of microiontophoretic ejection are indicated by bars above the rate records; the numbers above bars give ejection currents in nA.

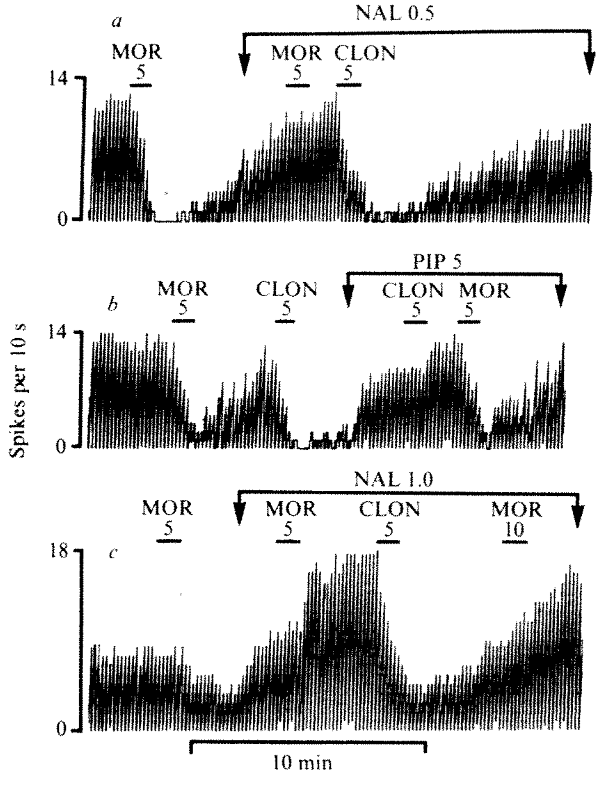

Table 1 Incidence of neuronal responses to microiontophoretically applied morphine and naloxone in LC and adjacent areas of control and morphine-dependent rats

Preparation	Region (no. of cells)	Morphine		Naloxone	
		% Cells activated	% Cells depressed	% Cells activated	% Cells depressed
Control rats ($n = 5$)	Locus coeruleus ($n = 10$)	0	100	0	0
	Cerebellum, Purkinje cells ($n = 6$)	33	0	0	0
	Mesencephalic nucleus of fifth nerve ($n = 5$)	0	0	0	0
	Reticular formation/central grey ($n = 10$)	10	10	0	0
Morphine-dependent rats ($n = 5$)	Locus coeruleus ($n = 10$)	0	100	100	0
	Cerebellum, Purkinje cells ($n = 5$)	40	0	0	0
	Mesencephalic nucleus of fifth nerve ($n = 5$)	0	0	0	0
	Reticular formation/central grey ($n = 12$)	8	8	8	8

In all cases, microiontophoretic currents were: +5nA, morphine; +0.5–1.0 nA, naloxone. Morphine was applied for 1 min; naloxone was applied 3 or more min. Purkinje cells were identified by climbing fibre bursts. The mesencephalic nucleus of the fifth nerve was identified by activation caused by displacement of mandible.

($n = 5$ cells; Fig. 1*b*). Figure 1*c* shows that in morphine-dependent rats (24 h after 4–5 daily pellet implantations) the inhibitory response of LC cells ($n = 10$) to microiontophoretic morphine was reduced compared with the controls (54% compared with 87%; $P < 0.01$, Student's *t* test). In all the dependent animals, the sustained microiontophoresis of naloxone on to LC cells produced a dramatic increase over baseline firing rate (mean 126%, $n = 10$ cells; Fig. 1*c*). Following naloxone, responses to microiontophoretically applied morphine were abolished. However, even during periods of naloxone-induced opiate-receptor blockade and withdrawal activation, the microiontophoresis of clonidine was still able to depress LC cell firing to below baseline rates (Fig. 1*c*). The uniform responses of LC cells to morphine and naloxone in both control and dependent animals were in sharp contrast to the relatively low incidence of effects in cells in areas immediately surrounding the LC (Table 1).

The first part of this study shows that tolerance develops to the powerful inhibitory effect of morphine on the firing of LC neurones. In fact, 24 h after 4–5 daily morphine pellet implantations, LC cells fired in a normal range, whereas 24 h after a single pellet spontaneous activity was markedly suppressed. In tolerant animals the direct application of naloxone to LC neurones by microiontophoresis induced a withdrawal response characterised by a >100% activation of firing. In other experiments (not reported above) the intravenous administration of naloxone (0.02 mg per kg) to dependent (but not control) rats also produced a dramatic increase in LC cell firing; this increase was reversed by intravenous clonidine. However, because of the generalised nature of the withdrawal reaction produced by systemically administered naloxone, it cannot be known with certainty that the effects of LC cell firing represent a direct action within the LC. It has been reported that the iontophoretic application of naloxone to cortical neurones in morphine-dependent rats induces an increase in neuronal firing[21]. In the present study, at the same low microiontophoretic ejection currents which were used in the LC, most neurones in areas immediately surrounding the LC (cerebellum, mesencephalic nucleus of the fifth nerve, central grey/reticular formation) were not responsive to morphine and did not display naloxone-induced withdrawal. The marked sensitivity and high selectivity of LC neurones for opiates and opiate antagonists in this region of the brain is consistent with previous studies[6–8].

The results of this study also indicate that morphine and clonidine act at independent LC-cell receptors, as the opiate antagonist naloxone blocks morphine but not clonidine whereas the α antagonist piperoxane blocks clonidine but not morphine. Previous studies, in which morphine and D-amphetamine were administered by the systemic route, also suggest that opiate receptors and adrenergic receptors which regulate LC cells are distinct, as naloxone blocked the LC-inhibitory action of morphine but not that of the indirectly acting adrenergic agent D-amphetamine[6]. The present study extends this work by showing that specifically within the LC itself naloxone antagonises morphine but not the α_2-adrenergic agonist clonidine. In addition, reciprocal selectivity has been shown by the fact that the α blocker piperoxane antagonised clonidine but not morphine. Although morphine and clonidine thus seem to act on independent receptors within the LC, it is notable that they have similar depressant effects on overall LC cell activity. These observations provide a basis for the proposal that the α_2 agonist clonidine might suppress certain symptoms of opiate withdrawal by means of a parallel but independent action on cell activity[17]. Moreover, a perpetuation of a state of dependence is avoided as clonidine acts on a non-opiate receptor. Of course there are opiate receptors at diverse sites within the central nervous system[12,13,22], some of which presumably do not overlap with the location of α_2 adrenoceptors. Nevertheless, the effectiveness of clonidine in suppressing opiate withdrawal in humans suggests that significant components of the opiate-withdrawal syndrome may be due to increased noradrenergic activity in areas such as the LC which are affected in a like manner by both α_2 adrenoceptors and opiate receptors[17]. It is also possible that at some sites clonidine could suppress opiate withdrawal through an action on non-adrenergic receptors (for example, histamine receptors[23]). However, the actions of clonidine in the LC would seem to be through an α adrenoceptor as they can be blocked selectively by the α antagonist piperoxane.

I thank D. E. Redmond and M. S. Gold for discussions, and P. Greengard for the morphine pellets used in this study. Supported by USPHS grants MH-17871, MH-14459 and the State of Connecticut.

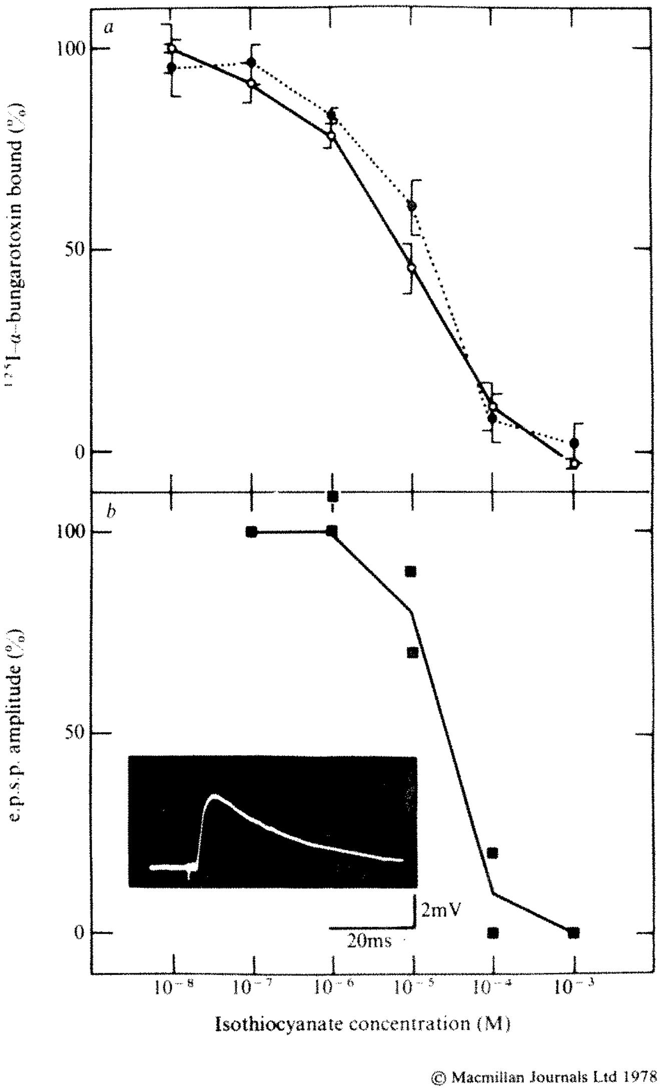
Insect acetylcholine receptors as a site of insecticide action

ACETYLCHOLINE is thought to be an excitatory neurotransmitter at synapses in the insect central nervous system (CNS) and does not seem to be involved in insect neuromuscular transmission[1,2]. Most of the current generation of insecticides are inhibitors of the enzyme acetylcholinesterase which hydrolyses acetylcholine, terminating its synaptic actions[3]. Far less attention has been given to other components of cholinergic synapses which might constitute potential sites of action of insecticidally active molecules. These include the presynaptic synthesis of acetylcholine involving the enzyme choline acetyltransferase, the mechanism of transmitter release and the postsynaptically located acetylcholine receptor molecules. The present study demonstrates that an isothiocyanate compound and nicotine, both of which show insecticidal activity, are agonists for an acetylcholine receptor in the CNS of the cockroach *Periplaneta americana*.

2-Isothiocyanatoethyltrimethylammonium iodide, synthesised as a potential insecticide, was found to be a potent inhibitor of choline acetyltransferase partially purified from fly heads[4]. In the same study the dissociation constant for the enzyme–inhibitor complex was found to be 0.06 μM. No significant inhibition of fly-head acetylcholinesterase was detected at a concentration of 100 μM (ref. 4). The possibility of a cholinergic presynaptic site of action in the insect CNS was therefore tested by perfusing the terminal abdominal ganglion of *Periplaneta* with saline containing 2-isothiocyanatoethyltrimethylammonium iodide (normal saline composition in mM: NaCl, 208.6; KCl, 3.1; $CaCl_2$, 5.4; $NaHCO_3$, 2.0; *p*H 7.0). Transmission at the cercal-nerve giant-fibre synapses, for which acetylcholine is the putative transmitter[5,6], was monitored by oil-gap (single-fibre) and sucrose-gap recording techniques[7]. A slow progressive block of the evoked excitatory postsynaptic potential (e.p.s.p.) might have been expected because of the time required both for access of the compound to the intracellular enzyme choline acetyltransferase and for the utilisation of existing stores of acetylcholine. Instead, however, a rapid reduction of the evoked e.p.s.p. and postsynaptic membrane resistance was detected, accompanied by depolarisation of the postsynaptic membrane at concentrations above 10^{-5} M (ref. 7). These results suggested a direct action of the isothiocyanate on the postsynaptic membrane, possibly on the acetylcholine receptors. The present study was designed to test this hypothesis by examining the binding of the isothiocyanate to an insect acetylcholine receptor and comparing this quantitatively with its ability to produce postsynaptic blockade. For comparison, parallel experiments were carried out using nicotine, which is both an insecticide and a potent ganglionic blocking agent in insects[5].

As a receptor probe we have used ^{125}I-α-bungarotoxin, which binds specifically to nicotinic acetylcholine receptors of vertebrates[8,9]. An ^{125}I-α-bungarotoxin-binding component with the expected properties of an acetylcholine receptor[10] has been characterised in fly heads of *Drosophila melanogaster*[11–14] and *Musca domestica*[13], in brain tissue of the moth *Manduca sexta*[15], and in abdominal nerve cords of *P. americana*[16]. In view of the controversy over the relationship between α-bungarotoxin-binding activity and the nicotinic acetylcholine receptor in the vertebrate CNS[17,18], it is important to note that α-bungarotoxin blocks transmission at the cercal-nerve giant-fibre synapses in the terminal abdominal ganglion of *Periplaneta*[19]. To determine whether the isothiocyanate and nicotine bind to acetylcholine receptors, we have compared their ability to

Fig. 1 *a*, Concentration dependence of inhibition by 2-isothiocyanatoethyltrimethylammonium iodide of ^{125}I-α-bungarotoxin binding to extracts of both whole flies (*D. melanogaster*) and cockroach abdominal nerve cords (*P. americana*). Results are expressed as a percentage of toxin bound to extract in the absence of the isothiocyanate. Each point is the average of three replicates and vertical bars denote 1 s.d. Concentrations for 50% inhibition of toxin binding are estimated to be 6.9×10^{-6} M (*Drosophila*; ○) and 1.6×10^{-5} M (*Periplaneta*; ●). *b*, Effects of various isothiocyanate concentrations on the amplitude of the evoked e.p.s.p. recorded from the cercal-nerve giant-fibre synapses in the terminal abdominal ganglion of *P. americana* using a modified sucrose-gap technique[7]. Concentration for 50% suppression of the e.p.s.p. is estimated to be 2.6×10^{-5} M. Inset shows the e.p.s.p. recorded in normal saline (100%).



0028-0836/78/0276—0188$01.00

inhibit ^{125}I-α-bungarotoxin binding to particulate extracts with their competence to modify transmission at a synapse that can be blocked by α-bungarotoxin. Differential centrifugation techniques described previously have been used to prepare the particulate form of the receptor from *D. melanogaster*[11] (20,000*g* pellet from whole flies) and *P. americana*[16] (40,000*g* pellet from abdominal nerve cords). Extract equivalent to either 0.005*g* flies (*Drosophila*) or to 0.001*g* abdominal nerve cords (*Periplaneta*) was incubated with a solution of either 2-isothiocyanatoethyltrimethylammonium iodide or nicotine in Krebs original Ringer buffer, *p*H 7.4 (ref. 20) at 21° C for 30 min. Such mixtures were then combined with ^{125}I-α-bungarotoxin in Krebs Ringer buffer, *p*H 7.4, containing 0.1% bovine serum albumin and incubated in microfuge tubes (Beckman, no. 314326) at 21° C for a further 30 min, before centrifugation at 30,000*g* (30 min, 4° C).

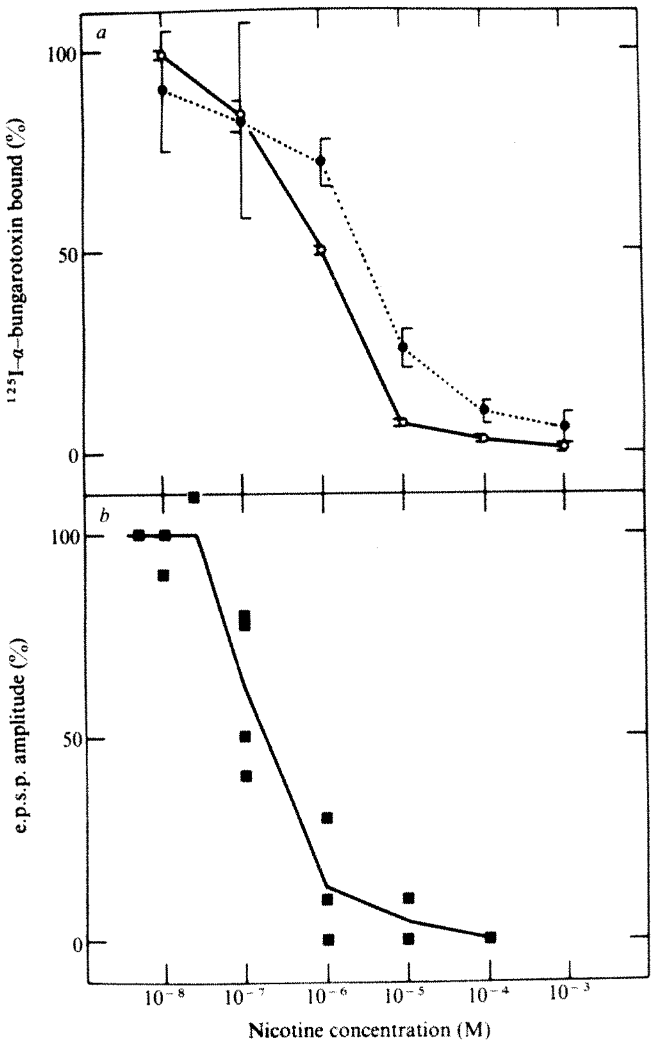


Fig. 2 *a*, Concentration dependence of inhibition by nicotine of ^{125}I-α-bungarotoxin binding to extracts of both whole flies (*D. melanogaster*) and cockroach abdominal nerve cords (*P. americana*). Results are expressed as percentage of toxin bound to extract in the absence of nicotine. Concentrations for 50% inhibition of toxin binding are estimated to be 1.0×10^{-6} M (*Drosophila*; ○) and 3.0×10^{-6} M (*Periplaneta*; ●). Each point is the average of three replicates and vertical bars denote 1 s.d. *b*, Effects of various concentrations of nicotine on the amplitude of the evoked e.p.s.p. recorded from the cercal-nerve giant-fibre synapses in the terminal abdominal ganglion of *P. americana*. Concentration for 50% suppression of the e.p.s.p. is estimated to be 2.0×10^{-7} M.

After removal of the supernatant fluid, pellets were rinsed twice and counted at 80% efficiency in a gamma counter (Searle model 1197). Background binding determined as the amount of ^{125}I-α-bungarotoxin bound to heat-inactivated extract was routinely subtracted. Similar levels of background binding were noted in the presence of 10^{-3} M nicotine. 100% binding was defined as the amount of ^{125}I-α-bungarotoxin bound in the absence of added ligand. In this way it was shown that 2-isothiocyanatoethyltrimethylammonium iodide inhibited toxin binding to the insect extracts (Fig. 1*a*). The concentrations of isothiocyanate producing 50% inhibition of toxin binding (ID_{50}) were estimated to be 1.6×10^{-5} M (*Periplaneta*) and 6.9×10^{-6} M (*Drosophila*). It was also demonstrated that nicotine inhibited toxin binding somewhat more effectively than the isothiocyanate (Fig. 2*a*). The ID_{50} concentrations for nicotine were estimated to be 3.0×10^{-6} M (*Periplaneta*) and 1.0×10^{-6} M (*Drosophila*). This value obtained for *Drosophila* extract agrees with the ID_{50} value of 0.5×10^{-6} M previously estimated for the inhibition by nicotine of toxin binding to *Drosophila* extract[11]. The ability of these insecticidally active compounds to inhibit α-bungarotoxin binding is similar to that found for acetylcholine in the presence of an anticholinesterase (ID_{50} = 2.8–7.9×10^{-6} M for *Drosophila*)[11].

In parallel electrophysiological experiments on the terminal abdominal ganglion of *Periplaneta*, changes were followed in the amplitude of the monosynaptic e.p.s.p. evoked by electrical stimulation of cercal nerves and recorded by the sucrose-gap technique from the cercal-nerve giant-fibre synapses during the perfusion of the ganglion by the test compounds. The ganglionic nerve sheath was routinely split to facilitate access to the synapses of the applied compounds[7]. It was estimated that 50% inhibition of the e.p.s.p. was produced by a concentration of 2.6×10^{-5} M isothiocyanate (Fig. 1*b*). As shown in Fig. 2*b*, the concentration of nicotine estimated to produce 50% block of the e.p.s.p. was 2.0×10^{-7} M. Just as nicotine was more effective than the isothiocyanate in inhibiting toxin binding *in vitro*, it was also a more potent inhibitor of the e.p.s.p

We have demonstrated that 2-isothiocyanatoethyltrimethylammonium iodide produces half-maximal block of ^{125}I-α-bungarotoxin binding to the insect extracts (*Periplaneta* CNS and *Drosophila* whole flies) at concentrations similar to those producing half-maximal suppression of e.p.s.p. amplitude at a central synapse in *Periplaneta* which can be blocked by α-bungarotoxin[19]. Differences between the factors affecting biochemical and physiological techniques make direct comparison of absolute ID_{50} values difficult. However, within each technique the order of effectiveness of test compounds can be determined and then compared between techniques. Studies with nicotine have shown that this cholinergic ligand is more potent than the isothiocyanate both in its ability to inhibit ^{125}I-α-bungarotoxin binding and in its actions on the postsynaptic membrane. The data indicate that the synaptic actions of both these insecticidally active molecules can be accounted for by their binding to the α-bungarotoxin-sensitive acetylcholine receptors, as they both inhibit toxin binding at physiologically relevant concentrations.

Our results provide direct evidence for an insect acetylcholine receptor as a site of insecticide action and thereby emphasise the need for detailed comparative studies on the properties of insect and vertebrate cholinergic receptors. We have demonstrated that the α-bungarotoxin binding assay could provide a rapid way to screen potential insecticides for action on a cholinergic receptor. We have also, indirectly, illustrated the difficulties in attempting a rational design of insecticide molecules. It should be recalled that 2-isothiocyanatoethyltrimethylammonium iodide, which has been shown to be effective at the postsynaptically located α-bungarotoxin-sensitive acetylcholine receptor, was originally designed as an inhibitor of the presynaptically located enzyme choline acetyltransferase.

We thank Dr A. C. Baillie of Fisons Ltd for 2-isothiocyanatoethyltrimethylammonium iodide. L.M.H. is a McKnight Scholar in Neuroscience and acknowledges the additional financial support of the US NSF and the Council for Tobacco Research USA.

Morphine and β-endorphin influence the secretion of the endocrine pancreas

OPIOID PEPTIDES[1-3] are present in high concentrations in those areas of the brain and gastrointestinal tract[4] in which opiate receptors[5] are numerous and a biological response to opiates well established[6]. The report of immunoreactive enkephalin in the pancreas[4] raised the possibility that a similar association between the presence of endogenous peptide and opiate receptors might exist in this organ and would be manifested by a biological response to these agents. We report here that an exogenous opiate and an endogenous opioid peptide both exert biological effects upon the endocrine pancreas that are compatible with the presence of opiate receptors in the islets of Langerhans.

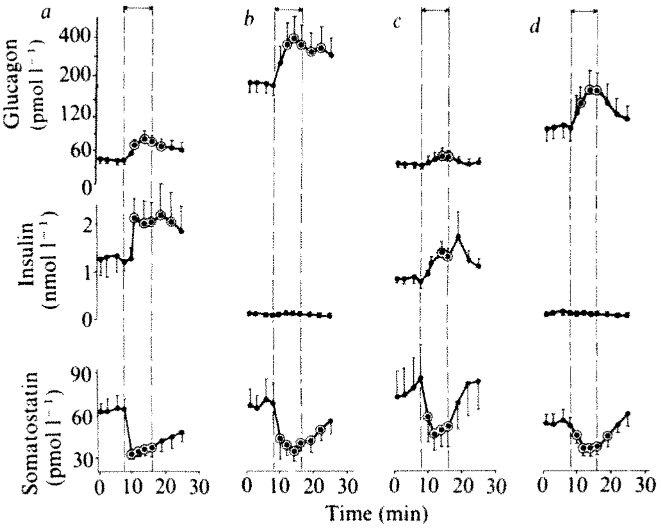
We examined the effects of morphine and the opioid peptide β-endorphin on the release of immunoreactive insulin, glucagon and somatostatin from the isolated perfused dog pancreas. We used the preparation of Iversen and Miles[7], in which the pancreas is perfused without recirculation at a rate of 20 ml min^{-1}. Somatostatin-like immunoreactivity (SLI) was measured by a radioimmunoassay using antiserum R101 of Arimura[8,9], and insulin and glucagon by a modification of previously described methods[10,11].

Perfusion of morphine sulphate (Wyeth) at a concentration of 3 μmol l^{-1} in the presence of 5.5 mM glucose lowered SLI levels by 50% ($P < 0.05$) at 2 min, while insulin and glucagon levels almost doubled ($P < 0.05$), each reaching a peak at 4–6 min (Fig. 1*a*). When glucose was omitted from the perfusate (Fig. 1*b*), SLI levels again declined by approximately 50% ($P < 0.05$); however, as expected, baseline glucagon levels were higher and the peak glucagon level was fourfold greater than in the presence of 5.5 mM glucose, while baseline insulin concentrations were lower and did not rise measurably in response to the morphine.

We then tested the effects on islet hormone secretion of the opioid peptide, β-endorphin (synthesised at the Salk Institute by N. Ling), at a concentration of 54 nmol l^{-1}, 1/50 of the molar concentration of morphine, both in the presence of 5.5 mM glucose and in its absence. As in the case of morphine, in the presence of 5.5 mM glucose SLI release was suppressed by 50% and again statistically significant inhibition occurred within 2 min ($P < 0.05$), preceding the peak changes in insulin and glucagon (Fig. 1*c*). Mean glucagon concentrations rose slightly but significantly ($P < 0.05$), and insulin levels increased almost twofold, with peaks once again occurring at 4–6 min ($P < 0.05$). Omission of glucose from the perfusate was again associated with higher baseline levels of glucagon and an exaggerated glucagon response to β-endorphin ($P < 0.05$), while baseline insulin levels were lowered and the insulin response to the opioid peptide abolished. However, SLI levels were suppressed ($P < 0.05$) as in the presence of glucose (Fig. 1*d*).

The similarity of the islet responses to two dissimilar substances, an opiate alkaloid and an endogenous peptide, suggested that they were mediated by a specific receptor mechanism. If so, these effects should be prevented by a specific antagonist. We therefore examined the effects of the opiate antagonist, naloxone hydrochloride (Endo), perfused at 11 μmol l^{-1}. Naloxone perfused alone did not affect either glucagon or SLI release, although insulin concentration increased significantly ($P < 0.05$) (ref. 9, Fig. 2*a*). Naloxone blocked the morphine-induced changes in glucagon and SLI, but the insulin response was reduced by only about 50% (Fig. 2*b*, left panel). The effects of β-endorphin on glucagon, somatostatin and insulin were completely abolished by the opiate antagonist ($P < 0.05$) (Fig. 2*b*, right panel).

Fig. 1 The effect of morphine (*a*, *b*) and β-endorphin (*c*, *d*) on immunoreactive glucagon, insulin and somatostatin release from the isolated dog pancreas. Note the change in scale on the glucagon axis. Significant differences ($P < 0.05$, ref. 9) from baseline are indicated by encircled dots. The pancreas was surgically isolated from healthy conditioned male dogs weighing 20–30 kg and then perfused with a semisynthetic buffer, as previously described[5]. The perfusate consisted of a Krebs–Ringer-bicarbonate buffer with 4% Dextran T-70 (Pharmacia), 10 mM arginine, with or without 5.5 mM glucose. Morphine sulphate or porcine β-endorphin were infused for 8-min periods on one or two occasions in each pancreas. The pancreatic effluent was collected at 1-min intervals and frozen for subsequent radioimmunoassay. *a*, 10 mM arginine + 5.6 mM glucose; morphine 3 μmol l^{-1}; $n = 6$. *b*, 10 mM arginine, no glucose; morphine 3 μmol l^{-1}; $n = 6$. *c*, 10 mM arginine + 5.5 mM glucose; β-endorphin 54 nmol l^{-1}; $n = 7$. *d*, 10 mM arginine, no glucose; β-endorphin 54 nmol l^{-1}; $n = 7$.



0028-0836/78/0276—0190$01.00

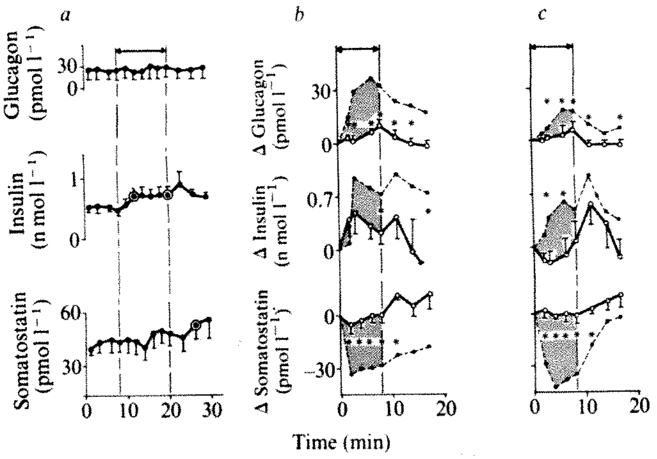


Fig. 2 *a*, The effect of naloxone alone on immunoreactive glucagon, insulin and somatostatin release from the isolated dog pancreas. Significant differences ($P < 0.05$, ref. 12) from baseline are indicated by encircled dots. *b*, The effect of naloxone on morphine and β-endorphin induced changes in islet cell function. Morphine (3 μmol l^{-1}) or β-endorphin (54 nmol l^{-1}) were perfused for 8 min, beginning 4 min after the start of the naloxone perfusion. The responses during naloxone perfusion are compared to those in the absence of naloxone, and the differences are indicated by the stippled areas. The hormone concentration immediately before the perfusion of morphine or β-endorphin was used as the baseline in order to derive the changes induced by each substance over and above changes induced by naloxone alone. Statistically significant ($P < 0.05$, ref. 13) differences between the two groups are indicated by an asterisk. The perfusate of all experiments illustrated in Fig. 2 contained 5.5 mM glucose, and each experiment was carried out in a different pancreas. *a*, 10 mM arginine + 5.5 mM glucose; naloxone 11 μmol l^{-1}. *b*, Morphine; ○, naloxone added; ●, no naloxone. *c*, β-Endorphin; ○, naloxone added; ●, no naloxone. Values are means from six experiments.

Thus, it seems that the opiate alkaloids and endogenous opioid peptides are capable of altering islet cell function, probably via a specific receptor mechanism. A similar observation has recently been made with respect to the exocrine pancreas[14], long known to be responsive to morphine[15]. The presence of endocrine cells with enkephalin-like immunofluorescence in islets of the pancreas[16] raises the possibility that locally secreted enkephalin may influence islet cell function through nearby receptors, and that circulating β-endorphin, which is released from the corticotrophs of the pituitary in response to stress[15], might also exert such effects. The failure of naloxone to produce any effect on basal SLI and glucagon release argues against a persisting 'tonic' *in vitro* action of endogenous opioid peptides that can be blocked by the antagonist, but does not exclude such activity *in vivo* in an intact pancreas.

Hyperglycaemia has been observed after morphine injection in various species[18–20] and was attributed to central effects of the drug[21], mediated by the adrenergic nervous system[22], but no studies of the acute effects of morphine on islet hormone release have ever been reported. The possibility that direct stimulation of glucagon release may contribute to hyperglycaemia, especially in states of insulin deficiency such as diabetes mellitus, should be considered.

Finally, it should be noted that in these studies significant suppression of SLI always preceded significant changes in insulin and glucagon release. This raises the possibility that a primary event in opiate action upon the islets is suppression of endogenous somatostatin and release of insulin and glucagon from its inhibitory influence.

We thank Drs Roger Guillemin and Nicholas Ling for β-endorphin and Dr Akira Arimura for antiserum R101. This work was supported in part by VA Institutional Research Support Grant 549-8000-1; NIH Grant AM 027000; NIH contract N01-AM-62219; Salk Institute—Texas Research Foundation.

Induction of ornithine decarboxylase by nerve growth factor dissociated from effects on survival and neurite outgrowth

SEVERAL eukaryotic cell types respond to a variety of hormones or growth-promoting agents by a rapid induction of ornithine decarboxylase (ODC) activity (for reviews see refs 1, 2). This enzyme[2] and the polyamines whose synthesis it catalyses[1] have been suggested in turn to play a part in mediating subsequent cellular responses to such hormone or replication factors. Among the agents shown to affect ODC activity is nerve growth factor (NGF), a protein which affects the differentiation and survival of sympathetic and responsive sensory neurones[3]. MacDonnell *et al.*[4] have demonstrated that treatment of rat superior cervical ganglia with NGF causes a rapid (maximal by 6–7 h), transcription-dependent increase in ODC activity. NGF treatment has also been reported to increase ODC activity in rat brain[5]. Such findings have led to the suggestion that ODC may mediate other responses of neurones to NGF[4]. We show here, however, that suppression of ODC activity and of its induction do not interfere with several other responses to NGF such as promotion of neurite outgrowth, maintenance of survival and increase in cell size. Such findings may be relevant to the possible role of ODC induction in other differentiating systems.

One particularly useful model system for studying the mechanism of action of NGF is a clonal line (designated PC12) of rat adrenal phaeochromocytoma cells[6]. In serum-containing medium and in the absence of NGF, such cells display several differentiated properties associated with adrenal chromaffin cells[6,7]. When treated with nanogram levels of NGF, however, PC12 cells cease replication and acquire certain features of sympathetic neurones, including the formation of extensive neurites[6] (Fig. 3) and electrical excitability[6]. One of the advantages of the PC12 line is that it may be used to study the initial

0028-0836/78/0276—0191$01.00

events whereby NGF affects target cells (normal responsive neurones, in contrast, have already been exposed to the factor *in vivo* before experimental intervention). Moreover, PC12 cultures maintained with serum can be used as adequate non-NGF-treated controls (normal sympathetic neurones, in contrast, require NGF for survival[9] and hence, NGF-untreated material may be dying and unsuitable as controls).

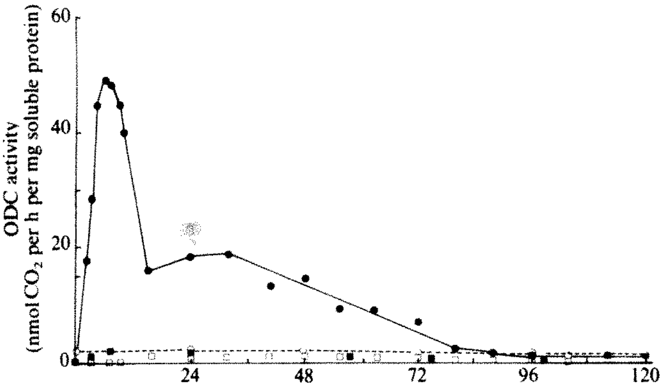

Fig. 1 Specific activity of ornithine decarboxylase in PC12 cultures after various times of treatment as indicated. PC12 cells (~250 generations after their isolation) were cultured on collagen-coated 35-mm tissue culture dishes (Falcon) as described previously[6,7], in 1.5 ml of medium. Because the introduction of fresh complete growth medium (85% RPMI 1640, 10% horse serum and 5% fetal calf serum)[6] to cultures itself caused a 15-fold induction of ODC activity within 6 h, the experiments shown here used cultures maintained in medium containing 1% horse serum. The latter medium did not induce ODC activity and hence long-term experiments (in which medium was changed every other day) could be carried out with a stable baseline. Although growth in such medium was slowed (doubling time ~6 d), neither cell viability nor responsiveness to NGF were affected. (It may also be noted that qualitatively identical results to those shown here were also obtained with cultures maintained in complete growth medium.) Cultures treated with 5-hexyne-1,4-diamine or 1,3-diaminopropane (Aldrich) were preincubated with these compounds for 14 and 1 h, respectively, before addition of NGF. Mouse salivary gland 2.5S NGF[10] was added in 5 μl of culture medium to a final concentration of 50 ng ml^{-1}. Addition of the same volume of culture medium containing the diluted buffer (0.1 M sodium acetate, *p*H 5.5) in which the stock NGF (0.5 mg ml^{-1}) was dissolved had no effect on ODC activity. After various times of treatment, cultures were collected by scraping the cells into 400 μl of assay buffer (see below). The cells were broken by sonication, and the sonicates quick-frozen on dry ice and stored at −20 °C (<7 d) until assayed. Before assay, samples were thawed and centrifuged for 10 min at 12,000 *g* in a Brinkmann microcentrifuge. ODC activity was measured in the supernatant fraction by minor modifications of the assay described by Pegg and Williams-Ashman[11]. Assay buffer was 50 mM Tris-Cl, *p*H 7.4, containing mM sodium EDTA, 5 mM dithiothreitol, 0.1 mM pyridoxal phosphate and 1 mM D,L-ornithine. For each assay, 300 μl of cell supernatant (or of buffer for blanks), 150 μl of assay buffer and 50 μl of assay buffer containing 0.45 μCi of [1-^{14}C]-D,L-ornithine (specific activity 53 mCi $mmol^{-1}$; New England Nuclear) were mixed and incubated for 1 h at 37 °C in a disposable 17 × 100-mm polystyrene tube (Falcon) with a centre well suspended from a rubber stopper (Kontes Glass). Released ${}^{14}CO_2$ was trapped in 100 μl of NCS solubilizer (Amersham) absorbed on a piece of filter paper in the centre well. Assays were terminated by injecting 0.5 ml of 50% trichloroacetic acid into the tube through the stopper. After overnight incubation, the trapped ${}^{14}CO_2$ was counted using Instagel scintillant (New England Nuclear). Assays were linear for the range of protein used (60–300 μg per sample). Specific activities are based on protein concentrations determined by the method of McGuire *et al.*[12]. Values are averages of determinations on duplicate cultures. ○, Untreated; ●, NGF; □, NGF + 1 mM 1,3-diaminopropane; ■, NGF + 0.1 mM 5-hexyne-1,4-diamine.

Figure 1 shows the results of an experiment in which ODC activity was measured in PC12 cultures at various times of treatment with or without 50 ng per ml 2.5S mouse submaxillary gland NGF[10]. In NGF-containing cultures, ODC activity underwent a rapid increase which was maximal within 5–8 h of treatment. A smaller secondary increase was also present during the second day of exposure. For 12 separate experiments, the ODC activities (±s.e.m.) in cultures treated with or without NGF for 6 h were 41.0 ± 3.1 and 2.2 ± 0.5 nmol CO_2 released per h per mg protein, respectively. This rapid NGF-dependent increase in ODC activity seemed to require RNA transcription, as it was completely blocked (to levels of <0.9 nmol CO_2 released per h per mg protein) by exposure to the RNA synthesis inhibitors actinomycin-D (1 μg ml^{-1}) or camptothecin (10 μg ml^{-1}).

The effect of NGF on ODC activity was not generalised to all cell types. Exposure to NGF for 6 h did not alter the ODC activities in cultures of two cell lines (3T3 fibroblasts[13] or C_6 glioma cells[14]) which have no known biological response to the factor. The mean ($n = 3$) ODC activity ±s.e.m. (in nmol CO_2 formed per hr per mg protein) in 3T3 cultures was 20.5 ± 0.7 (no NGF) and 21.0 ± 1.2 (1,000 ng ml^{-1} NGF) and in C_6 cultures 5.3 ± 0.7 (no NGF) and 4.8 ± 0.2 (1,000 ng ml^{-1} NGF).

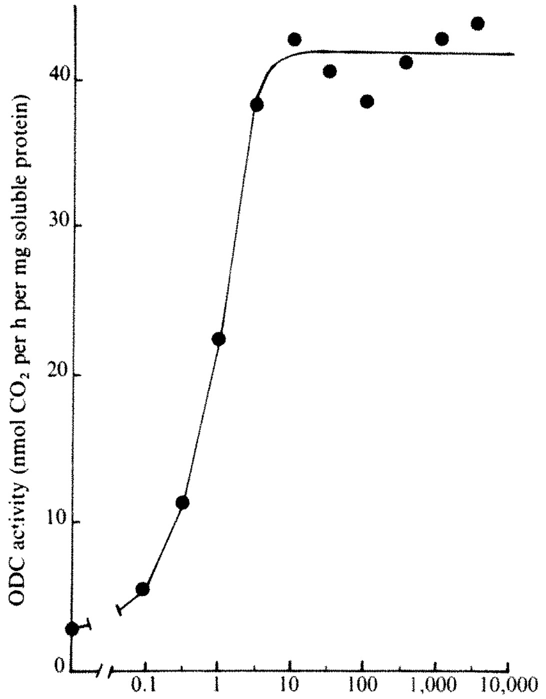

Fig. 2 ODC activity in sister PC12 cultures 6 h after exposure to the indicated concentration of NGF. Cultures were maintained as in Fig. 1 and assays were carried out as described in the legend to Fig. 1. Values are averages of determinations on duplicate cultures.

Figure 2 shows a dose–response relationship (after 6 h of treatment) between NGF concentration and ODC activity in PC12 cultures. Stimulation of activity was detectable at the lowest NGF concentration tested (0.1 ng ml^{-1}) and was maximal at 3–10 ng ml^{-1} (0.1–0.3 nM) NGF. The latter concentrations correspond to those required for stimulation of neurite outgrowth from PC12 cells[6,15] and are similar to the dissociation constant reported for NGF with membrane receptors on mammalian sympathetic ganglia[16].

The finding that NGF treatment causes a rapid increase in ODC activity of responsive cells raises the question as to whether such an increase is required for other responses to the factor. To test this, two methods were used to suppress ODC activity in PC12 cells, treatment with 1 mM 1, 3–diaminopropane (DAP) or with 0.1 mM 5-hexyne-1,4-diamine (HDA). The former suppresses ODC activity by apparently causing a specific inhibition of synthesis of the enzyme[17,18], and the latter is a specific, irreversible inhibitor of ODC activity[19] that is effective within living cells (R. Rando, personal communication). As shown in Fig. 1, treatment of PC12 cultures with either compound totally blocked the effect of NGF on ODC activity. At 6 h after addition of NGF, ODC activities in DAP- and HDA-treated cultures were 1 and 4%, respectively, of those in non-inhibited NGF-treated cultures. Nevertheless, treatment with these inhibitors did not affect either cell viability or the ability of NGF to promote neurite outgrowth. Figure 3 illustrates the morphological response of PC12 cells to NGF with or without continuous suppression of ODC activity.

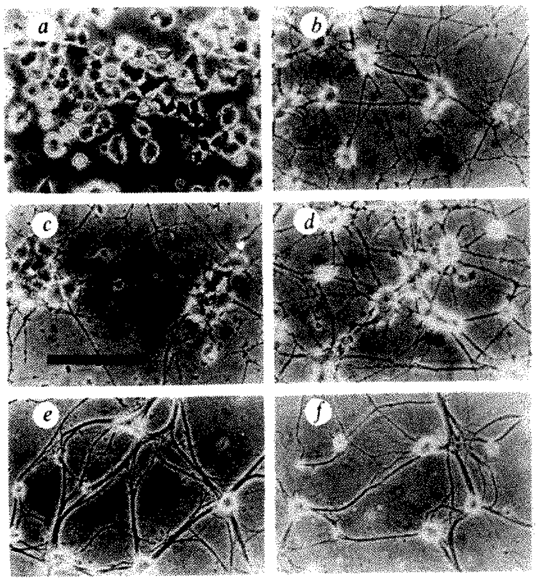

Fig. 3 Phase-contrast micrographs of PC12 cells maintained in culture conditions as described in Fig. 1 and treated for 6 d with (A) no NGF, (B) NGF, (C) NGF plus 1 mM 1,3-diaminopropane, or (D) NGF plus 0.1 mM 5-hexyne-1,4-diamine, and of dissociated cell cultures of 11-d embryonic chick sympathetic neurones maintained for 6 d (E) with NGF or (F) with NGF plus 1 mM 1,3-diaminopropane. Cultures of chick sympathetic neurones were prepared as previously described[20] except that the presence of non-neuronal cells was substantially reduced by treatment with 0.6 μM cytosine arabinoside on days 2–4 *in vitro*. Sympathetic neurones treated with 0.1 mM 5-hexyne-1,4-diamine resembled those shown in (E) and (F). Treatment with the ODC inhibitors in the absence of NGF promoted neither neurite outgrowth from PC12 cells nor survival of neurones. Bar, 100 μm.

Table 1 Effect of inhibitors of ODC activity on NGF-dependent survival of PC12 cells in serum-free medium

Addition to culture medium (RPMI 1640)	Cells per dish ($\times 10^{-4}$)
None	0.3 ± 0.2
0.1 mM 5-hexyne-1,4-diamine	0.3 ± 0.1
1.0 mM 1,3-diaminopropane	0.2 ± 0.1
50 ng ml^{-1} NGF	10.6 ± 1.7
50 ng ml^{-1} NGF + 0.1 mM 5-hexyne-1,4-diamine	12.2 ± 2.3
50 ng ml^{-1} NGF + 1.0 mM 1,3-diaminopropane	9.4 ± 1.5

PC12 cells (8×10^4) were plated in serum-free culture medium in the presence of the indicated compounds and maintained for 7 d. Cell number per dish was then determined as described elsewhere[6]. Values are means ± s.e.m. of four determinations.

As may be seen in Fig. 3, NGF treatment also causes an increase in the size of PC12 cell bodies[8]. This increase still occurred when induction of ODC activity was blocked. Measurement of cell body diameters (where diameter is defined as (length of short axis + length of long axis)/2) from photographs of cells gave mean ± s.e.m. ($n = 25$ in each case) values of 9.4 ± 0.2 μm for untreated cells, and 13.6 ± 0.5 μm, 13.9 ± 0.4 μm and 13.5 ± 0.4 μm, respectively, for cultures treated for 6 d with NGF, NGF + 1 mM DAP, and NGF + 0.1 mM HDA. Such results did not seem to be due merely to cell flattening, as similar changes in size were also apparent when the cells were detached from the dish and allowed to round up in suspension.

Another effect of NGF on PC12 cells is to promote their survival (as well as their morphological differentiation) in serum-free medium[15]. That is, if serum is withdrawn from PC12 cultures, the cells die. However, in the presence of NGF in serum-free medium, the cells survive and extend neurites. In the present experiments, NGF was found to induce ODC in serum-free conditions. The average ODC activities in duplicate cultures treated for 6 h with or without NGF in serum-free culture medium were 26.8 and 1.8 nmol CO_2 released per h per mg protein, respectively. However, as shown in Table 1, suppression of ODC activity in serum-free PC12 cultures by either DAP or HDA did not block the effect of NGF on cell survival.

Experiments were also carried out with dissociated cell cultures of 11-d chick embryo sympathetic neurones. These cells require NGF for their survival and neurite outgrowth[3,20]. Inclusion of either mM DAP or 0.1 mM HDA in NGF-containing culture medium at the time of plating of such cells did not have an apparent effect on their survival or neurite outgrowth (see Fig. 3) even though ODC activity (measured at 6 d after plating) was suppressed to only 2 and 12%, respectively, of that in control cultures (38.4 pmol CO_2 released per h per mg protein).

Our findings strongly suggest that although NGF can induce ODC activity in responsive cells, neither increased levels of the enzyme molecule nor of its enzymatic activity are required for NGF-dependent survival or stimulation of neurite outgrowth. This conclusion raises several alternatives concerning the role of ODC induction in the mechanism of action of NGF. One is that induction of ODC is causally related to other effects of NGF which were not tested here. Another possibility is that ODC induction bears no causal relationship to other actions of NGF and that it is itself a 'dead end' or terminal consequence of other events related to the interaction of NGF with its target cells. The latter possibility raises the issue of the relevance of ODC induction to the mechanism of action of other agents[1,2] which affect cell differentiation.

We thank Mei-Nian Chou and Judith Graham for their assistance, Dr R. Rando for his advice and for 5-hexyne-1,4-diamine, and Dr Gordon Guroff for his comments, and we acknowledge that his group has also obtained results similar to those reported here. This work was supported by grants from the USPHS (NS11557 and NS12200), National Foundation-March of Dimes and Sloan Foundation.

Cyclic-AMP-induced differentiation in neuroblastoma is independent of cell division rate

CLONED, cultured mouse neuroblastoma cells, when grown in conditions which restrict cell division, extend neurites[1–6] and increase the activity of neurotransmitter-related enzymes[7–9]. Treatments that can induce this differentiation include lowered serum concentrations[3], prostaglandins[4], phosphodiesterase inhibitors[5] and analogues of cyclic-3′,5′-AMP (cyclic-AMP)[6,10–11]. These treatments have been proposed to act by elevating intracellular cyclic-AMP levels, but because they also inhibit cell division it has been difficult to determine whether their effects are due directly to cyclic-AMP or indirectly to inhibition of cell division[12]. As neurite growth and enzyme elevation occur during the interphase portion of the cell cycle (and are retarded during cell division), cyclic-AMP may simply allow differentiation by stopping the cell cycle in interphase[3]. The butyryl analogues of cyclic-AMP, in particular, markedly restrict cell division (ref. 10; see also Fig. 1*a*). Because butyrate, which can dissociate from the dibutyryl analogue of cyclic-AMP, can itself markedly inhibit cell division we reasoned that other analogues may exist which are not inhibitors of cell division but which effectively mimic the action of cyclic-AMP. We report here that 8-bromo-cyclic-3′,5′-AMP (8Br-cyclic-AMP) effects biochemical and morphological changes in the neuroblastoma clone NBD-2 (ref. 9) without concomitant inhibition of cell division.

As shown in Fig. 1 *a*, 8Br-cyclic-AMP (up to 1 mM) does not inhibit the rate of cell division in this neuroblastoma culture but, in fact, below 0.3 mM produces an increase in the cell division rate (150–160% of control). In contrast, both dibutyryl-cyclic-AMP (Bt_2-cyclic-AMP) and Na butyrate inhibit cell division. At 1 mM, Bt_2-cyclic-AMP inhibits division ~50% and Na butyrate inhibits cell division almost completely. (0.2 mM Na butyrate produces an inhibition of cell division comparable to 1 mM Bt_2-cyclic-AMP.)

Table 1 Enzyme activities in the NBD-2 cells

Treatment	TH	CAT	AChE	Cell no. per culture*
	Product per h per 10^6 cells†			
	(pmol)	(pmol)	(μmol)	
Control	50±9	3.3±0.3	5±3	6.4±0.8
1 mM 8Br-cyclic-AMP	810±12	9.9±1.0	6±3	6.2±1.1
1 mM Bt_2-cyclic-AMP	760±10	10.2±0.5	120±11	2.9±0.3
0.2 mM butyrate	62±8	3.9±0.8	6±4	2.9±0.5

NBD-2 cells were plated at 0.4×10^6 cells per 60 mm diameter culture dish in 5 ml of F-12 medium supplemented with 10% newborn calf serum. Treatments were added after 24 h, and cells were collected for assay 48 h later. The enzyme assays used are described in detail elsewhere[9].

* Values are expressed in terms of 10^6 cells after 72 h in culture per 10^6 cells originally plated.

† All values represent the mean ±SEM of four determinations.

On the other hand, 8Br-cyclic-AMP and Bt_2-cyclic-AMP, but not Na butyrate, induce comparable increases in neurite extension (Fig. 1*b*). Thus, the cyclic-AMP moiety, as opposed to decreased cell division, seems to be responsible for the morphological changes in these cells. However, because the data in Fig. 1 are taken from a population of cells at a single time point, it is still possible that only some of the cells undergo neurite extension (and diminished cell division) while other cells increase their rate of division. For example, at low 8Br-cyclic-AMP concentrations (little effect on neurite extension) perhaps a small, more rapidly dividing subpopulation is being revealed, and as the 8Br-cyclic-AMP concentration is raised this effect becomes relatively balanced by another subpopulation of cells now undergoing neurite extenstion (and not dividing).

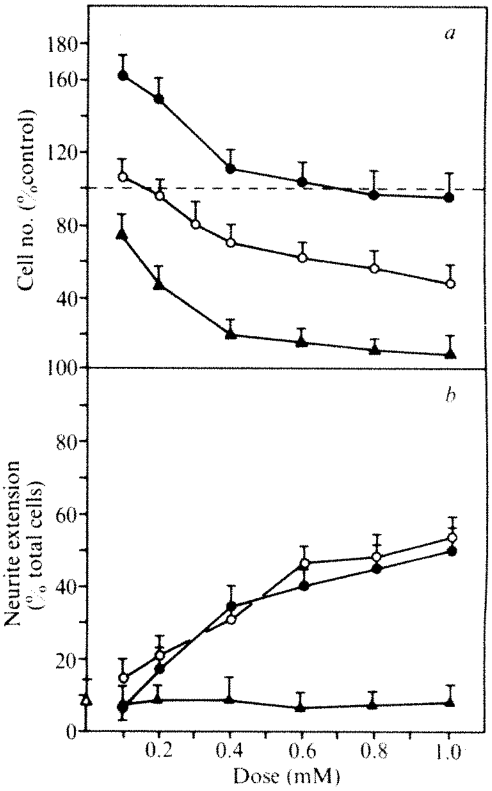

Fig. 1 Cell division and neurite extension in cultured NBD-2 neuroblastoma cells. NBD-2 neuroblastoma cells, isolated as previously described[9], were plated at 0.4×10^6 cells per 60-mm diameter culture dish in 5 ml of F-12 medium supplemented with 10% (v/v) GG-free newborn calf serum. Treatments were begun 24 h later and continued for 48 h. Drugs and media were changed every 24 h. *a*, Cell numbers were determined by haemocytometry on the basis of trypan blue exclusion[9]. More than 99% of the cells were trypan blue excluding. Values represent the mean ±SEM of four separate experiments in which duplicates were run for each determination. *b*, The number of cells extending neurites was determined in each sample by counting the number of cells (out of 200) with processes greater than twice the length of the cell body. Values represent the mean ±SEM of four separate experiments as in *a*. △, Control; ○, Bt_2-cyclic-AMP; ●, 8Br-cyclic-AMP; ▲, butyrate.

Examination of 8Br-cyclic-AMP-treated neuroblastoma cells with time-lapse cinematography (3 d) revealed, however, that every cell within the microscopic field underwent both neurite extension and division during each 24-h period. Figure 2 is taken from one time-lapse film and shows that the 8Br-cyclic-AMP-treated cells exhibit both neurite extension and cell division. The cells spent the majority of time in a differentiated state (Fig. 2 *a,d,j*) and, with rare exception, were de-differentiated only immediately before and after division. For example, the average

0028–0836/78/0276—0194$01.00

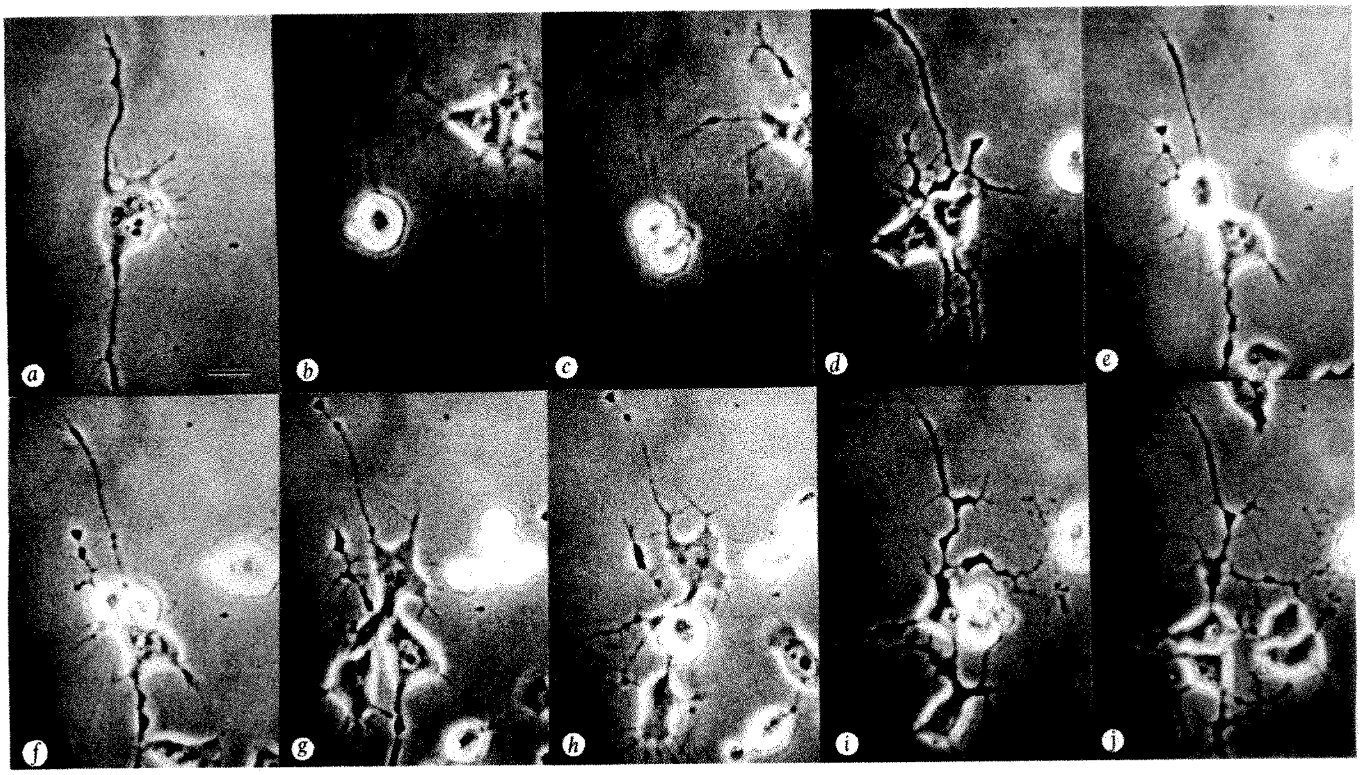

Fig. 2 Differentiation and division in NBD-2 cells treated with 8Br-cyclic-AMP. NBD-2 cells were plated at 0.1×10^6 cells per 2 ml F-12 medium supplemented with 10% newborn calf serum in Rose chambers and gassed with 5% CO_2 95% air. After 24 h, the cells were treated with 1 mM 8Br-cyclic-AMP and time-lapse cinematography was begun ~10 h later. For the first 15 h (*a*) the cell remained in a differentiated state. It withdrew its processes and remained rounded up (*b*) for 40 min whereupon it divided (*c*). After 50 min both cells exhibited processes at least twice the diameter of the cell body (*d*). The cells remained in this differentiated state for 18 h until one of the cells de-differentiated and divided over a 54-min period (*e*, *f*). The newly divided cells differentiated (*g*, 100 min) and the second cell subsequently de-differentiated (*h*, 2 h) and divided (*i*, 40 min). The cells differentiated (*j*) and all four cells remained differentiated for the duration of this particular film (>15 h). The photography was taken on a Zeiss RA microscope with phase contrast optics in a hot room at 37 °C. A Sage series 500 cinephotomicrographic apparatus with a Bolex H167 16-mm movie camera was used with 0.5 s exposures at 1/s. The calibration bar represents 10 μm.

time in a de-differentiated state was 77 ± 12 min ($n = 10$ randomly selected divisions).

Stopped-frame analysis at 4-h intervals showed that 40–60% of the treated cells exhibited neurite extension at any given time, in agreement with Fig. 1*b*. Thus, as this division rate is comparable to untreated cells[9] and as growth curves of 8Br-cyclic-AMP-treated and untreated cells are identical (data not shown), the increase in neurite extension cannot be attributed to a decrease in division rate *per se*.

Concomitant with the changes in cell morphology produced by the two cyclic-AMP analogues, tyrosine hydroxylase (TH, EC 1.14.16.2) and, to a lesser extent, choline acetyltransferase (CAT, EC 2.3.1.6) activities are increased (Table 1). The fact that these changes in enzyme levels are induced by both 8Br-cyclic-AMP and Bt_2-cyclic-AMP (but not Na butyrate at a concentration that produces an inhibition of cell division equivalent to 1 mM Bt_2-cyclic-AMP) implies that the cyclic-AMP moiety of these compounds is also capable of modifying the biochemisty of the cultured neuroblastoma cells in a manner independent of an effect on cell division rate. Interestingly, this was not the case for a third enzyme examined. 1 mM Bt_2–cyclic-AMP, but not 0.2 mH Na butyrate or 1 mM 8Br-cyclic-AMP, dramatically elevated the activity of acetylcholinesterase (AChE, EC 3.1.1.7) (Table 1). Although the elevation of this enzyme is often associated with decreased cell division[7,13–15], the lack of effect of Na butyrate (0.2 mM, matched for effects on cell division) argues against a simple cause. However, as higher Na butyrate concentrations do induce comparable increases in AChE activity (not shown), some butyrate (either attached or dissociated from cyclic-AMP) or butyrate-cyclic-AMP interaction may be responsible for this effect.

These results, then, strongly support the contention that cyclic-AMP can influence neuroblastoma morphology and biochemistry in a manner independent of changes in cell division rate. Further, 8Br-cyclic-AMP seems to be better suited than at least the dibutyryl analogue of cyclic-AMP for studies in which effects on cell division may complicate interpretation of the results.

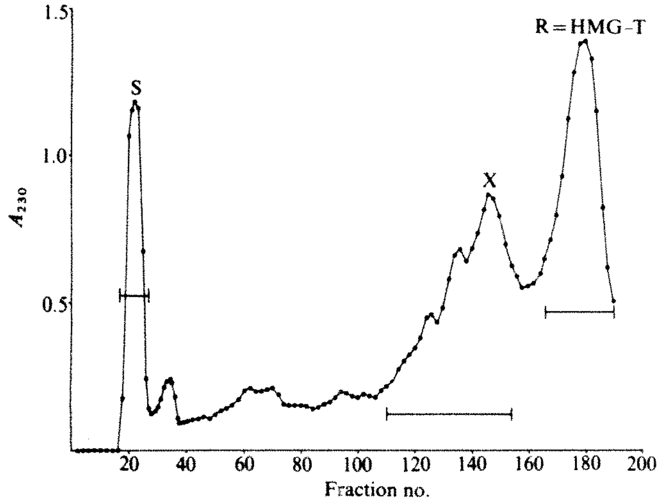
Free ubiquitin is a non-histone protein of trout testis chromatin

A NON-HISTONE chromosomal protein extracted from trout testis chromatin by 0.35 M salt, protein S, (ref. 1) has now been purified to homogeneity and its primary structure determined (Fig. 3) and shown to be identical with that of the thymus protein, ubiquitin[2-4] (originally called thymopoietin) and sequenced by Schlesinger *et al.*[5]. Ubiquitin was previously reported in chromatin by Goldknopf *et al.*[6] as a component of protein A-24 in which it is covalently bound by the α-carboxyl group of its C-terminal glycine to the ε-amino group of lysine 119 of histone H2A in an isopeptide linkage[7]. Goldknopf and Busch[8] have reported that protein A-24 is a component of the core nucleosomes of rat liver chromatin being present in quantities sufficient for it to be linked to H2A in 10–20% of the total nucleosomes. The present studies indicate clearly that ubiquitin can also occur as a free polypeptide in trout testis chromatin and is readily extracted by 0.35 M NaCl. Moreover, free trout testis ubiquitin (protein S) is rapidly released together with HMG-T (ref. 9) (and small amounts of Hl) during limited micrococcal nuclease digestion of trout testis chromatin and is probably also located in the linker regions of the chromatin. DNase I digestion does not release free ubiquitin preferentially[10]. In view of the pronounced biological effects of free ubiquitin on membrane adenyl cyclase of immature thymocytes[3,4] and the ability of ubiquitin to promote the differentiation of these cells into mature T cells[3,4], its occurrence in chromatin raises the possibility of a role of ubiquitin in cell differentiation and differential gene expression.

Trout testis ubiquitin (protein S) was isolated from washed chromatin by the method described by Goodwin *et al.*[11] for preparation of calf thymus HMG-proteins and was purified by chromatography on a BioRex 70 cation exchanger[1] (Fig. 1); ubiquitin was eluted as a sharp peak at the passthrough volume of the column and on electrophoresis either in starch[12] (Fig. 2*a*), Triton-polyacrylamide[13] gels (Fig. 2*b*) or SDS-polyacrylamide gels[14] (Fig. 2*c*), it migrated as a single component with a minor slower running contaminant. The mobility of trout testis ubiquitin is identical with that of authentic calf thymus ubiquitin (Fig. 2*b*). Comparison with the mobility of the molecular weight protein markers on the SDS-polyacrylamide gel (Fig. 2*c*) gives molecular weights of 8,500 for both trout testis and calf thymus ubiquitin.

Fig. 1 Ion-exchange chromatography of trout testis HMG-proteins on a column (2 × 50 cm) of BioRex 70 (200–400 mesh) eluted with a linear gradient formed by mixing 500 ml of 2% with 500 ml of 11% guanidinium chloride[1]. The fractions containing the protein peak emerging at the pass-through volume of the column (S) were combined, exhaustively dialysed in membranes of Sepraphore III (MW cutoff 3,500) against distilled water and lyophilised. The yield of protein S was approximately 17 mg per kg trout testis.



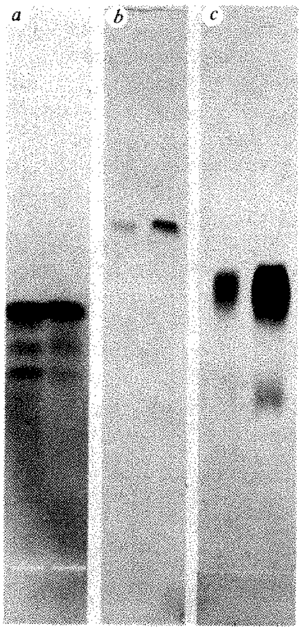


Fig. 2 Gel electrophoresis in three systems of trout testis ubiquitin (protein S) with markers of authentic calf thymus ubiquitin. *a*, Starch gel electrophoresis in aluminium lactate buffer[12]. *b*, Triton-polyacrylamide[13] gel electrophoresis (15% polyacrylamide, 0.22% Triton X-100, 5% acetic acid). *c*, SDS-polyacrylamide[14] gel electrophoresis (15% polyacrylamide, 1% SDS, Tris-glycine, *p*H 6.8). Molecular weight markers of insulin (6,000), lysozyme (14,300) and cytochrome *c* (12,000) were included in order to estimate the MW of the ubiquitins. The ubiquitin bands in (*c*) were excised, hydrolysed[15] and their amino acid compositions determined using a Beckman Model 121 M analyser equipped with a Systems AA integrator. Amino acid compositions were reduced to the most likely stoichiometry using the least squares fit program of Osawa and Tanaka[24].

Amino acid analyses show that trout testis and calf thymus ubiquitin are identical in composition within experimental error. In these analyses, the trout testis ubiquitin major component was eluted from the SDS-polyacrylamide gel and hydrolysed[15]. We have also carried out a completely independent amino acid sequence analysis of trout testis ubiquitin by automatic Edman degradation of the intact protein as well as a series of peptides obtained by trypsin cleavage after protection of the lysyl residues by maleylation[5], by chymotryptic cleavage, by cleavage with staphylococcal protease[16], by chemical cleavage at aspartyl residues in 0.2 M acetic acid[17] and by chemical cleavage at the single tyrosyl residue at position 59 with *N*-bromosuccinimide. The single methionyl residue is amino-terminal and it was found that cleavage with cyanogen bromide yielded free homoserine lactone and a fragment (residues 2–74) indistinguishable from the intact protein by gel electrophoresis.

The only area of uncertainty in the sequence is between residues 68 and 71, as it has not yet been possible to recover from trout testis ubiquitin a peptide containing the histidyl residue located at position 68 of calf thymus ubiquitin. A summary of the peptides leading to the deduction of the complete sequence of trout testis ubiquitin is given in Fig. 3. Details of the sequence analysis will be published elsewhere. This sequence is identical to that described for calf thymus ubiquitin by Schlesinger *et al.*[5] with the possible exception of residues 68–71. Our independent determination of the complete sequence of ubiquitin from a salmonid fish testis and the demonstration of the identity of at least 71 of the 74 positions with ubiquitin from calf thymus shows that the structure of ubiquitin is probably as highly conserved during evolution as that of the arginine-rich histones H3 and H4. A limited

N-terminal sequence is available for a plant ubiquitin (from celery)[4] and shows that six of the eight residues in this region are identical but the sequence is too limited to make a conclusion about the evolutionary conservation of ubiquitin in the plant kingdom. Note that a radioimmunoassay developed by Goldstein *et al.*[4] for ubiquitin detects the protein in vertebrates, invertebrates, plants, fungi and a variety of bacteria so it is likely that there has been only limited divergence in the major antigenic determinants during evolution.

Table 1 Amino acid composition of calf thymus ubiquitin and trout testis protein S

Ubiquitin has been noted previously as a constituent of protein A-24 of calf thymus or rat liver nuclei[6,8] in which it is covalently bound by an iso-peptide linkage[7] from a C-terminal glycine residue to the ε-amino group of lysine 119 of histone H2A to produce a branched protein. The identification of one 'arm' of this protein with calf thymus ubiquitin was made when Hunt and Dayhoff[18] noted that a sequence of 40 residues at the N-terminus of protein A-24 was identical with calf thymus ubiquitin (the H2A arm is blocked to Edman degradation in the sequencer by its N-terminal acetyl group). The molecular weight of A-24 has been reported as 27,000 by SDS-polyacrylamide electrophoresis[6] but there is a discrepancy between this value and the sum of the molecular weights of ubiquitin (8,451) and H2A (14,000). It is possible that A-24 may migrate anomalously in SDS-polyacrylamide gels, as both components, ubiquitin and H2A have strongly hydrophobic regions and could bind additional detergent molecules. The second discrepancy is that Schlesinger *et al.*[5] originally reported that the C-terminal residue of calf thymus ubiquitin was arginine, whereas the peptide containing the isopeptide linkage isolated by Goldknopf and Busch[7] was reported as comprising a sequence Gly-Gly, presumably at the C-terminus of the ubiquitin arm. In our sequence studies of trout testis ubiquitin we have noted heterogeneity at the C-terminus, 50% of molecules are terminated by arginine (Fig. 3, peptide CH-IV-1) and 50% by glycine (Fig. 3, peptide CH-IV-2) but we have not seen evidence of a Gly-Gly sequence at the C-terminus. Further work is required to establish whether protein A-24 contains sequences additional to the reported sequence of calf thymus and trout testis ubiquitin and which might account for the apparent extra size of calf thymus A-24. Application of the method of Goldknopf *et al.*[6] to trout testis chromatin in our hands has not, so far, yielded a protein corresponding to A-24.

When trout testis nuclei were digested to a limited extent with micrococcal nuclease in conditions which lead to the rapid digestion of the 'linker' regions of chromatin (that is, between nucleosomes)[19-23], we observed that ubiquitin was released into

Fig. 3 Alignment of peptides from trout testis ubiquitin and comparison with the amino acid sequence of calf thymus ubiquitin[5]. MT, peptides from tryptic digestion of maleylated ubiquitin; CH, chymotryptic peptides; SP, staphylococcal protease peptides. Automated sequence determination was performed on purified peptides or intact ubiquitin on a Beckman 890C protein sequencer using a programme similar to that of Edman and Begg[25] but replacing the Quadrol buffer with the volatile DMAA buffer. The 2-anilino-5-thiazolinone derivatives of the amino acids from the sequencer were identified and quantitated by amino acid analysis following back hydrolysis in 47% hydriodic acid at 150° for 20 h.

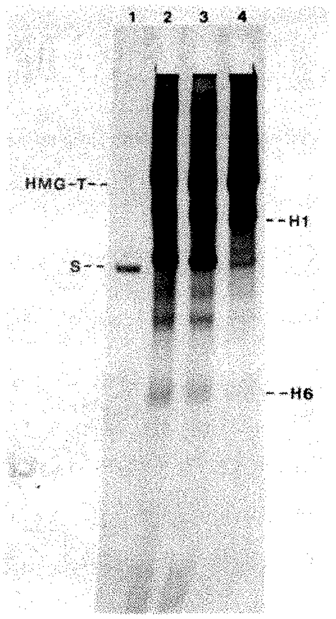

Fig. 4 Electrophoretic analysis of acid soluble proteins solubilised by micrococcal nuclease from trout testis nuclei. Micrococcal nuclease digestion of trout testis nuclei: trout testis nuclei were prepared as described previously[10]. The nuclear pellet was washed twice with RSB buffer (0.01 M Tris-HCl, *p*H 7.4, 0.01 M NaCl, 3 mM $MgCl_2$). Microscopic examination of the nuclear suspension revealed nuclei free of cytoplasmic tabs. Nuclei were resuspended in RSB buffer containing 1 mM $CaCl_2$ at a concentration of 10 mg ml^{-1} (200 A_{260}) of DNA and incubated with micrococcal nuclease (Worthington, 250 units ml^{-1}) at 37°C and digested to the extent of 5–10% of the input DNA. The reaction was terminated by chilling the tubes on ice and immediate centrifugation for 5 min at 1,000 *g* in a Sorvall HB-4 rotor. The supernatant was designated S_1 and used together with the pellet for protein extraction. Acid extraction of proteins and gel electrophoresis: chromosomal proteins were extracted from S_1 and pellet fractions by incubation of that fraction with 0.2 M H_2SO_4 for 1 h at 4°C, as described previously[10]. Three batches of trout testis nuclei, collected at different stages of maturation were digested with micrococcal nuclease to the extent of 10–15% solubilisation of the input DNA, as previously described. The acid soluble proteins from the soluble supernatant were analysed in 12% polyacrylamide gels containing 0.22% Triton X-100. This gel system allows complete separation of the histones[13] and also of HMG-T, ubiquitin (S) and H6. Electrophoresis was for 21 h at 300 V at 4°C. The gel was stained with amido black for 15 h and destained with 5% acetic acid. Slot 1 contains a sample of purified trout testis ubiquitin. Slot 2 shows the proteins solubilised after 15% digestion of middle-late testis nuclei. Slot 3: proteins solubilised after 12% digestion of middle-late testis nuclei. Slot 4: proteins solubilised after 8% digestion of late testis nuclei.

the soluble fraction together with the bulk of the HMG-T. The electrophoretic pattern in a Triton-containing polyacrylamide gel of proteins solubilised by micrococcal nuclease is illustrated in Fig. 4. Slots 2, 3 and 4 contain proteins released by the nuclease from three different batches of nuclei prepared from trout testis at various stages of maturation. In all three cases, it is clear that ubiquitin or protein S is released by the nuclease. The identity of the ubiquitin band was confirmed by excision of the stained bands and then subsequent acid hydrolysis and amino acid composition analysis. Each of the bands in slots 2, 3 and 4 showed amino acid compositions identical with the marker ubiquitin band (slot 1). Examination by gel electrophoresis of the proteins remaining in the nuclear pellet following micrococcal digestion (data not shown) indicates that no detectable band of ubiquitin remains following the nuclease treatment suggesting that ubiquitin is preferentially associated with linker regions in chromatin. However, the fraction represented by ubiquitin of the total proteins released by the nuclease in the soluble fraction varies in different batches of nuclei. This finding is consistent with our previous observations that the major protein released by micrococcal nuclease, namely HMG-T, also changes in concentration as a function of testis development.

Our finding of a free polypeptide in the low salt extractable non-histone fraction of trout testis chromatin which is virtually identical in primary structure with calf thymus ubiquitin indicates that ubiquitin is a true chromosomal protein which is widely distributed. The extreme conservation of its structure during evolution suggests that like the arginine-rich histones H3 and H4, ubiquitin has a vital structural role in chromatin. The fact that it constitutes only 2–5% of the concentration of the individual nucleosomal core histones further suggests that ubiquitin can only be present in a small sub-set of the chromatin and, therefore, that the conserved structure in which it is located is different from the bulk of the chromatin in the now well-established nucleosomal core and linker structure (beads-on-a-string).

Our experiments with micrococcal nuclease suggest that ubiquitin is present in an easily digested domain of chromatin which contains as a major protein constituent, the non-histone protein HMG-T. Furthermore, we have shown recently that during limited micrococcal digestion of trout testis chromatin, linker regions containing HMG-T (and ubiquitin) are rapidly solubilised and concomitantly, a sub-set of nucleosome core particles containing another non-histone protein, H6, is also released[22,23]. The DNA sequences present in this sub-set of nucleosomes are enriched five to tenfold in sequences hybridising with testis RNA and this degree of enrichment of DNA sequences is also confirmed by DNA-driven hybridisations[22,23]. Thus, there seems to be clear evidence of the localisation of three non-histone proteins, ubiquitin, HMG-T and H6 in a domain of chromatin enriched in DNA sequences which can be transcribed into cellular RNA. It is possible that these proteins, either individually or as elements of a pattern could provide recognition signals which are necessary but not sufficient in themselves for transcription of designated regions of chromatin.

We thank Dr Gideon Goldstein (Ortho Pharmaceutical Co.) for a sample of calf thymus ubiquitin and Dr E. H. Peters (Protein Laboratory, Faculty of Medicine, University of Calgary) for analysis of the C-terminal residue of trout testis ubiquitin by hydrazinolysis. This work was supported by the MRC of Canada.

UNIVERSITY OF SALFORD

CHAIR IN ORTHOPAEDIC MECHANICS

Applications are invited for the Chair in Orthopaedic Mechanics in the Salford Orthopaedic Appliance Unit which is a Joint Body of the University and the Salford Area Health Authority (Teaching).

Candidates should be qualified in engineering or science and should desirably have had clinical experience in the field of orthopaedics.

The salary will be within the professorial range, the minimum of which will be £9,443 p.a. (under review).

Applications should be received by the Registrar, University of Salford, Salford M5 4WT (from whom further particulars may be obtained) by December 18, 1978.

Please quote reference number ME/343/N. 8370(A)

THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH

DEPARTMENT OF ZOOLOGY

Applications are invited for the post of

RESEARCH ASSISTANT

tenable for two years under an S.R.C. funded project, on the biology of a nematode parasite of larval *Simulium* (Diptera).

Salary within the range £3,384 to £3,883 per annum.

Application forms and further information can be obtained from the Secretary, Department of Zoology, The University College of Wales, Penglais, Aberystwyth, to whom applications, naming two referees, should be sent within three weeks of the appearance of this advertisement.

8354(A)

THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH

DEPARTMENT OF GEOGRAPHY

RESEARCH IN HYDROLOGY

Applications are invited for the post of RESEARCH ASSISTANT commencing January 1, 1979, to work on a three-year project to determine the role of soil pipe discharge in streamflow generation in an upland catchment. The work involves the design and supervision of an instrument network, hydrograph analysis and computer modelling.

Candidates with an M.Sc. in Hydrology or a similar qualification preferred. Salary: £3,189 per annum.

Further information obtainable from Dr J. A. Jones, Department of Geography, University College of Wales, Aberystwyth, to whom applications should be submitted as soon as possible. 8355(A)

The Queen's University of Belfast

LECTURESHIP IN HUMAN GENETICS

Applications are invited for a lectureship in the Department of Medical Genetics from April 1, 1979 or such other date as may be arranged. Experience in biology, genetics not necessarily in the human field, medical sciences or cytogenetics is highly desirable. Responsibilities include teaching of human genetics to medical undergraduates. Initial placing, which will depend on experience and qualifications, will be made on the scale, under review, for lecturers: £3,885 to £7,755 with contributory pension rights under the F.S.S.U. or U.S.S.

Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. Closing date: December 8, 1978. (Please quote Ref. 78/N).

8352(A)

SHEFFIELD CITY POLYTECHNIC

DEPARTMENT OF HOTEL AND CATERING STUDIES AND HOME ECONOMICS

TECHNICIAN (FOOD STUDIES) —T1 or T2 (Post No. 13)

The person appointed will be required to work in areas where all aspects of food preparation, processing and presentation are taught to catering students at advanced level and will be required to prepare food and equipment for student use. A qualification in Food Technology or an allied subject would be appropriate.

For an appointment at T2 level, applicants should hold H.N.C., Advanced City & Guilds or equivalent or for an appointment at T1 O.N.C. or equivalent.

Salary Scale: T1 £2,676 to £2,967; T2 £2,967 to £3,339, plus £312 per annum pay award plus qualification allowance.

Requests for an application form in writing only please to the Recruitment Section of the Personnel Department, Sheffield City Polytechnic (Dept. NA), Halfords House, Fitzalan Square, Sheffield S1 2BB. Completed forms should be returned by November 24, 1978. 8334(A)

Anglian Water Authority

QUALITY OFFICERS – 2 Posts
Ref: R2S13 & R2S43 Grade 4

£4,179 – £4,476 p.a.

inclusive of supplements

Applications are invited for the above two posts, initially based in Cambridge, with possible transfer to Bedford or Ely area offices at a later date in the case of post R2S43. Preference will be given to persons possessing an appropriate degree or the I.W.P.C. Diploma, with experience in the water quality field and a knowledge of geochemistry would be advantageous in the case of post R2S13.

Duties include development control, under the appropriate statutes, aspects of solid wastes disposal investigations and monitoring, the provision of technical information and various field surveys as appropriate, under the direction of the Quality Planning Officer and/or field inspections, investigations of pollutions and other matters, sampling surveys and the determination of consent conditions under the direction of the appropriate Area Quality Officer.

Water Industry conditions of service are applicable and Regular car allowances are currently payable.

Application forms may be obtained from the Divisional Scientist at the address below, telephone Cambridge 61561 (Miss Hobbs) to whom they should be returned by Monday 27th November, 1978:—

GREAT OUSE RIVER DIVISION
Great Ouse House, Clarendon Road

UNIVERSITY OF SOUTH FLORIDA

8 NEW FACULTY POSITIONS FOR THE DEPARTMENT OF MARINE SCIENCE

The Department of Marine Science at the University of South Florida, St Petersburg, announces the establishment of up to 8, new faculty positions. Marine Science at USF has been designated by the Board of Regents for the State University System for special funding by the State Legislature for its development of a graduate Center of Excellence. The Florida Institute for Oceanography, also located in St Petersburg, provides research vessel use and equipment for oceanographers in the State University System.

Application from persons in the following oceanographic specialties are encouraged:

> Phytoplanktonology, Marine Animal Physiology, Fishery Biology, Microbiology, Organic Geochemistry, Physical Chemistry, Radiochemistry, Geotechnical Properties of Sediments, Carbonate Petrology/Sedimentation, and High Resolution Geophysics.

Rank and salary will depend upon professional experience and accomplishment. The minimum for a nine month appointment for Professor is $24,000; Associate Professor, $17,000; and Assistant Professor, $15,000. The positions are fully State supported and tenure earning. Duties will involve approximately 75% research and 25% teaching.

The new appointments may be made at any time prior to the 1979-80 academic year. Applicants must have the Ph.D. in fields appropriate to their specialties and promising records of research accomplishment. The closing date for the receipt of applications is January 1, 1979.

Applicants should send complete résumés with 3 references to Dr John C. Briggs, Department of Marine Science, University of South Florida, 830 First Street South, St Petersburg, Florida 33701. The University is an affirmative action equal opportunity institution.

8241(A)

Geologist

for research in seismo-stratigraphy

The Royal Dutch/Shell Exploration and Production Laboratory at Rijswijk, near The Hague, carries out research in the field of exploration for and production of oil and natural gas. This research is closely related to the exploration and production efforts of Shell operating companies. The work, which in many cases is carried out as a multidisciplinary team effort, concentrates on the development and introduction of new techniques and the search for practical solutions to problems.

In the Geophysics Department of this laboratory work goes on in the latest developments in seismology as applied to oil exploration. We have a vacancy in this department for a sedimentary geologist to carry out research on the stratigraphic interpretation of seismic data. This will include the recognition and mapping of depositional sequences as well as more detailed interpretation. Preference will be given to candidates who have completed a Ph.D. in geology. They must be familiar with mathematics and statistics and preferably have some experience in seismic interpretation.

We can offer training opportunities both within and outside your professional field. Working hours are flexible to suit personal requirements. You must be prepared to undertake assignments overseas if necessary.

Travelling and other reasonable expenses will be paid for interviews in London and The Hague. Financial assistance will be given for the removal of household and personal effects to The Netherlands.

If you are interested in this position please write, with full details, to:

Shell International Petroleum Company Limited, Recruitment Division PNEL/12 (N1), Shell Centre, London SE1 7NA.

Shell

8369(A)

THE UNIVERSITY OF LEEDS
ASTBURY DEPARTMENT OF BIOPHYSICS

Applications are invited for two temporary posts of

POSTDOCTORAL RESEARCH FELLOW

in a group carrying out structural studies of enzymes as part of a continuing programme of work on the enzymes of folate metabolism being carried out under the supervision of Professor A. C. T North and Dr A. J. Geddes with support from the Science Research Council and Yorkshire Cancer Research Campaign.

One post of for a

CRYSTALLOGRAPHER

preferably with experience in protein crystallography, to continue the determination of the structure of dihydrofolate reductase which has reached an advanced stage. The appointment at present available is for a fixed term of nine months.

The second post is for a worker with experience in

PROTEIN CHEMISTRY, EXPERIMENTAL PATHOLOGY

or related fields to be responsible for the extraction, purification and structural studies of enzymes from human tissue. This appointment is for a fixed term of three years.

Starting salary in the range £3.883 to £5,129 on the IA Scale for Research and Analogous Staff (£3,883 to £6,555) (under review) according to age, qualifications and experience.

Preliminary enquiries to Professor A. C. T. North (Telephone (0532) 31751, ext. 6130) will be welcomed.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 42/1/D. Closing date for applications November 30, 1978. 8301(A)

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

VACANCIES

TECHNICIAN GRADE 5

IMMUNOLOGICAL RESEARCH
Two Posts

Post 1 H.N.C./degree with experience in immunology and laboratory organisation essential. Work will include tissue culture and animal research in infectious diseases.

Post 2 H.N.C./degree with experience in immunology and perhaps tissue culture. To join a clinical research project on the evaluation of immunological parameters in patients.

TECHNICIAN GRADE 3

PHYSIOLOGY
One Post

To assist with laboratory research on respiratory physiology and disease, including the use of experimental animals, There may also be a requirement to assist with practical classes for medical students. Emoluments (under review) Technician 5 £3,461 to £3,995, Technician 3 £2,963 to £3,335. Four weeks annual holidays plus 13 other days. For further details and application forms write, stating in which post interested, to the Establishment Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. Closing date November 23. 8295(A)

UNIVERSITY OF NAIROBI— KENYA

Applications are invited for the post o

SENIOR LECTURER

in the
DEPARTMENT OF CHEMISTRY

Applicants should have qualificatio in Physical Chemistry. In addition, th applicants must have a Ph.D. plu several years' teaching and researc experience. The appointee will b required to undertake the academi leadership in both teaching and research at the undergraduate and postgraduate levels.

Salary: K£2,988 to K£3,984 p.a (K£1=£1.35 sterling). The Britis Government may provide salary supplementation of £4,770 p.a. (sterling) fo married appointee or £3,252 p.a (sterling) for single appointee (reviewed annually and normally free o all tax) and provide children's education allowances and holiday visi passages. Family passages; non-contributory medical scheme; S.S.S.F. o F.S.S.U.; housing allowance.

Detailed applications (2 copies) wit curriculum vitae and naming 3 referee to be sent to the Registrar (Recruitment and Training), University o Nairobi, P.O. Box 30197, Nairobi Kenya, by December 11, 1978.

Applicants resident in U.K. shoul also send one copy to Inter-Universit Council, 90/91 Tottenham Court Road London W1P 0DT. Further details ma be obtained from either address.

8382(A)

Food Scientist/Technologist

for work of national and international importance

The Composition Sections of the Food Science Division provide a wide range of Scientific advice to those Divisions of the Ministry with executive responsibility for legislation on food and drink, and also maintains a close liaison with other Government departments having an interest in food composition and safety.

This appointment calls for an experienced food scientist/technologist to join a team concerned with protein based foods. The work will involve collating data on the composition, preparation and processing of raw materials and interpreting such data as a basis for advice related to present and future UK, EEC and International legislation. Little practical work is required but members of the Section must develop and maintain a broad interest in food processing, composition and legislation.

Candidates, normally aged under 32, must have a good honours degree or equivalent in food science, chemistry, biochemistry or closely related subject, coupled with at least 4 years experience in the food industry or a relevant area of research. Ability to collect and interpret information, prepare critical reviews, and participate in committee work at national and international levels advantageous.

Appointment as Senior Scientific Officer (£5620-£7360) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 1 December 1978) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote ref: SB/35/AE.*

Aquatic Biologist

■ Join small team testing the acute and chronic toxicity of pesticides on fish and other non-target organisms ■ Participate in planning laboratory studies ■ Assist with the long term planning of the work programme ■ Extended periods of field work in the Tropics possible.

Good hons degree in aquatic biology, ecology or related discipline Relevant experience preferred; at least 2 years required for HSO appointment Higher degree with research experience in the field advantageous Age normally under 30 Appointment as Higher Scientific Officer (£4560-£5910) or Scientific Officer (£3300-£4880) according to qualifications and experience Ref: SA/49/JA.

■ Application forms (for return by 1 December 1978) from Miss M Cole, Centre for Overseas Pest Research, College House, Wrights Lane, London W8 5SJ.

ALL THESE POSTS ARE OPEN TO MEN AND WOMEN.

8351(A)

Science Group
CIVIL SERVICE

BIRKBECK AND IMPERIAL COLLEGES
(University of London)
RESEARCH OFFICER IN INTERACTIVE COMPUTER GRAPHICS

Applications are invited for a three-ear post funded by the Science Research Council to work jointly with Professor D. M. Blow and Professor T. L. Blundell in the development of interactive computer graphics for tructure analysis of biological systems including proteins, drug molecules and macromolecule-water interactions.

The hardware includes an Evans and utherland Picture System II driven by PDP11/60 computer linked to an BM370/165 mainframe computer.

Applicants should have postgraduate xperience in computing, preferably with knowledge of mini-computers.

Salary according to qualifications and xperience, within Grade IA; entry point not exceeding £4,408 plus London Weighting, £450.

Applications to Professor T. L. Blundell, Department of Crystallography, Birkbeck College, Malet treet, London WC1E 7HX, telephone 1-580 6622. 8380(A)

NATIONAL COLLECTION OF TYPE CULTURES
MICROBIOLOGIST VACANCY
(Basic Grade)

Post for a science graduate in, preferably microbiology. The post includes maintenance of the bacterial strains of the Collection. About 3,500 strains of more than 300 species of medical and veterinary interest are kept, maintained in the freeze-dried state, and regularly checked for viability and characteristics. The National Collection of Type Cultures has extensive records and the graduate will also be involved in control of the supply of cultures. Opportunities for taxonomic research and identification of fresh isolates are available.

Salary according to age, qualifications and experience on the N.H.S. Whitley Council Scientific scale, plus London Weighting.

Applications to:- Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9. Tel: 01-205 7041. 8296(A)

ARC ANIMAL BREEDING RESEARCH ORGANISATION
Statistics and Computing Department

STATISTICIAN

Applications are invited for a Statistician to assist in the analysis of experimental data arising from research in various aspects of physiology and genetics of farm animals. The work will involve some computer programming and use of statistical program packages. Experience of computer programming in FORTRAN would be useful. The post is located at the Organisation's Field Laboratory at Roslin, near Edinburgh.

Applicants should have an honours degree with statistics as a main subject, or equivalent qualifications. Appointment will be as Scientific Officer (£2,839 to £4,415) with starting salary depending on qualifications and experience. Non-contributory superannuation.

Further information and application forms are available from the Secretary, ARC Animal Breeding Research Organisation, West Mains Road, Edinburgh EH9 3JQ. Closing date November 25, 1978. 8311(A)

OVERSEAS DEVELOPMENT

KNOW-HOW: vital to developing countries

Extension Agronomist Sudan

At Nuba Mountains Agricultural Production Corporation to assist with implementation of field programmes. Applicants should have University degree in Agriculture or related science, with at least 5 years' experience of crop production and extension work in developing country.

Appointment 3 years. Salary (UK taxable) in range £7000—£8500 pa plus tax-free overseas allowance in range £2080—£4555 pa (Ref 331).

The post is wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowances other benefits normally include paid leave, free family passages, children's education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.

High-Calibre Research Biochemist

Shell Research Limited are looking for a high-calibre Scientist to join the Fermentation and Microbiology Division of their Biosciences Laboratory at Sittingbourne, Kent.

You will join a multi-disciplinary team engaged in research on microbial extracellular polysaccharides. The work will involve studies on the biochemistry of microbial exopolysaccharide formation and on the physiology of the micro-organisms.

We would like to hear from people with either a Ph.D. or a good honours degree in an appropriate subject and with research experience in a relevant area of biochemistry. Knowledge of fermentation techniques would be advantageous but not essential. The ability to think and act innovatively will be considered important.

There is scope and opportunity for promotion and you will be expected to display the qualities needed to reach more senior positions. We will offer a competitive salary and assistance will be given with relocation expenses where appropriate. You will be able to join our pension fund, enjoy flexible working hours and work in well-equipped laboratories which are situated on a 450 acre farmland site. There are also excellent facilities for social and sports activities. Please write giving all the relevant details about yourself or telephone for an application form to:
Shell Research Limited, Recruitment Division (N1) PNEL/11, Shell Centre,
London SE1 7NA. Telephone: 01-934 2948. 8300(A)

Shell

IMPERIAL COLLEGE RESEARCH FELLOW

Postdoctoral Agricultural Scientist required for key post in research team working on the applications of trace element surveys to agriculture. Applicant should hold good degree in agriculture or soil science and have some experience of geology. Starting salary according to age and experience in the range £4,359 to £5,847 (including London Allowance) with U.S.S.

Applications to Dr I. Thornton, Applied Geochemistry Research Group, Department of Geology, Imperial College, London SW7 2BP.

EXCELLENT CAREER OPPORTUNITY for a

TECHNICAL PLANNING OFFICER

to join its BIOLOGY DEPARTMENT

The successful candidate will be responsible for:

a) advising on the implementation of the GLP standards

b) assisting with the planning of research projects

c) organizing the collation and storage of research data

Applicants should have a degree in the Biological Sciences. Past or present experience in the pharmaceutical industry is essential.

An excellent salary and comprehensive benefit program accompany this position.

Please, send Curriculum Vitae to Box No. 8310(A)
NATURE
3 Dyer's Buildings

BRITISH ANTARCTIC SURVEY

HIGHER SCIENTIFIC OFFICER/ SENIOR SCIENTIFIC OFFICER (BIOMETRICIAN)

An experienced BIOMETRICIAN is required by the Life Sciences Division of the British Antarctic Survey to take part in a number of research programmes, including the offshore biological programme which is a major investigation into physical and chemical features of the marine environmental, phytoplankton standing, crop and photosynthesis and aspects of krill, fish, bird and seal biology at South Georgia.

The management of these and other data bases, development of analytical methodology and provision of general biometrical advice will be amongst the successful applicants duties.

Qualifications: A degree in a mathematical or biological subject; plus at least two years relevant postgraduate experience for appointment as H.S.O., or at least four years for appointment as S.S.O.

Salaries: H.S.O., £4,101 to £5,448 per annum; S.S.O., £5,154 to £6,898 per annum. Starting salary may be above the minimum, according to age and experience.

The staff of the Council are not Civil Servants, but their pay and conditions of service are similar to those of the Civil Service. There is a non-contributory superannuation scheme.

For further details and an application form, please write stating full qualifications and experience to:

The Establishment Officer
British Antarctic Survey
Madingley Road, Cambridge CB3 0ET

Please quote Ref: BAS105.
Closing date: 30 November, 1978.

LABORATORY TECHNICIAN, OXFORD

Medical lab. tech. graduate preferred, trained in light and transmission electron microscopy required on January 1, 1979 to work in Oxford. Knowledge of day-to-day electron microscope an advantage. Manufacturer's contract for regular major service and breakdown maintained. Initial three-year contract on current Whitley Council scales. Apply for further details to: Director, Lepra, Fairfax House, Causton Road, Colchester, Essex CO1 1PU. 8367(A)

THE ROYAL VETERINARY COLLEGE

University of London
Division of Clinical Studies
DEPARTMENT OF MEDICINE

LECTURER IN VETERINARY MEDICINE

This vacancy is open to veterinary surgeons of some experience. The appointee will work in the department at North Mymms, Hertfordshire, and will be expected to take part in the general clinical work of the department but will have special responsibility in the area of cardiopulmonary disease of the companion animals. The appointee will be required to give instruction to undergraduates and pursue research in this speciality for which the department can provide excellent facilities.

SALARY SCALE (under review): £4,333 to £8,204 including London Allowance. Initial salary will be determined according to qualifications and experience. Superannuation under the Universities' scheme. Removal expenses up to £800 may be reimbursed in approved circumstances.

Further information can be obtained from Professor F. R. Bell, Head of the Department of Medicine—telephone Potters Bar 55486.

Application form and further written particulars available from the Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU (telephone 01-387 2898).

Applications must be received by November 30, 1978. 8292(A)

APPOINTMENTS WANTED

MARINE GEOPHYSICIST GEOLOGIST

20 years experience in off-shore oil, mineral search, teaching and research in Caribbean, Canada and Middle East. Available on short notice. Box No. 8308(A) c/o Nature, 8 Dyers Buildings, Holborn, London EC1N 2NR.

APPOINTMENTS VACANT

LKB
WALLAC

TECHNICAL WRITER FINLAND

WALLAC OY, a member of the international LKB group of companies requires an experienced technical writer for their marketing department.

The successful candidate will have a qualification in electronic engineering and preferably a knowledge of microprocessors and of primary concern an ability to communicate.

The position will be located in Turku which is a pleasant town in south west Finland.

A competitive salary with four weeks paid holiday, free medical care and subsidised meals are amongst the benefits offered. Assistance with relocation expenses will also be considered.

For further information please contact in the first instance: Mr P. L. Morris, LKB Instruments Ltd., 232 Addington Road, Selsdon, South Croydon, Surrey. Tel. No. 01-657 8822. 8368(A)

UNIVERSITY OF LONDON KING'S COLLEGE

TECHNICIAN GRADE 5

required in the Anatomy Department's Electron Microscope Unit. The successful applicant would have overall responsibility for the operation of the E.M. Unit and would also be responsible for the training of junior staff and advising academic staff, undergraduate and postgraduate students on the application of EM techniques. At present the Unit has one AEI EM 6B, and a JEOL 100CX with scanning facility. Applicants should possess an H.N.C. or equivalent qualification and relevant experience. Salary on scale £3,651 per annum rising to £4,185 per annum inclusive (under review). Four weeks annual holiday. College contributory pension scheme. Apply in writing with full details to: The Head Clerk, Ref. 204035/N, King's College London, Strand WC2R 2LS.

UNIVERSITY OF THE WITWATERSRAND JOHANNESBURG

CHAIR OF PHYSICAL CHEMISTRY

Applications are invited for appointment to the Chair of Physical Chemistry on the staff of the Department of Chemistry.

The salary will be in the range R12,474 to R15,939 per annum, the initial salary to be determined according to the qualifications and experience of the successful applicant. Benefits include an annual bonus, pension and medical aid facilities and a housing subsidy (if eligible).

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further particulars relating to this practice and to the above post are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg 2001, South Africa, with whom applications should be lodged by January 5, 1979. 8327(A)

Drug Metabolism

Section Heads

Biosciences Research Centre, Great Burgh, Epsom

As a result of the Company's expanding research activities, a new Drug Metabolism Unit has been created at the recently established Biosciences Research Centre at Great Burgh, near Epsom. The Unit which forms part of the Clinical Pharmacology Department will be equipped to a high standard and should be ready for occupation early in 1979. Its responsibilities will include the investigation of drug metabolism in experimental animals and man, with particular interest in the areas of biosciences and chemotherapeutic agents.

Three Section Heads are required who will assist the Head of the Unit in the equipping of the laboratories and the appointment of staff within their respective sections before the Unit becomes fully functional.

Analytical Biochemistry -

The Head of Analytical Biochemistry Section will be responsible for a team concerned with the development and application of methods for the quantitative analysis of drug substances and their metabolites in biological systems and for the design and initiation of pharmacokinetic studies. Candidates for this position should have broad experience in the use of H.P.L.C., G.L.C., GC-MS, automated analysis and other relevant analytical techniques used in modern biochemical analysis.

Chemistry-

The Head of Chemistry Section will be responsible for a team involved in the preparation of compounds labelled with radioactive or stable isotopes, which are required for metabolic studies in laboratory animals and man, and for preparing compounds necessary for progressing the Unit's activities. Candidates should have at least three years post-doctoral research experience in synthetic organic chemistry and possess a sound knowledge of the theoretical concepts of the subject. Experience in radio-chemical synthesis and in working with small amounts of substances would be a distinct advantage.

Metabolic Biochemistry -

The Head of Metabolic Biochemistry Section will be responsible for a team investigating the metabolic fate of pharmacological agents in laboratory animals and man. The successful candidate will have had at least three years post-doctoral experience in the field, be well informed on the theoretical concepts involved and possess a substantial knowledge of relevant practical techniques.

The nature of the work in the Drug Metabolism Unit will necessitate considerable liaison between the three Section Heads, the Head of the Unit, and other scientific staff.

The positions which are open to male and female candidates will command a competitive starting salary and a range of other benefits including non-contributory pension and free life assurance.

For an application form please telephone Burgh Heath 53344, Extension 208, or write to: **The Site Personnel Manager, Beecham Pharmaceuticals, Research Division, Biosciences Research Centre, Great Burgh, 1 Yew Tree Bottom Road, Epsom, Surrey.**

Pharmaceuticals

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF ELECTRONIC AND ELECTRICAL ENGINEERING

SENIOR RESEARCH ASSISTANT

Centralised Facility for Epitaxial growth of III-V Compounds

The Science Research Council has recently established in the Department a centre for the growth of III-V compounds, initially based on GaAs and InP and their alloys, by liquid phase epitaxy. The Senior Research Assistant will be responsible for helping to set up facilities for growing such layers and for investigating problems associated with their growth. There will be close interaction with other members of the existing group working on device and transport properties of these materials. Applicants, men or women, should preferably have a higher degree and significant experience of crystal growth. Tenable four years in the first instance; starting salary in range £3,883 to £5,367 depending on age and experience. Details from Professor P. N. Robson, Department of Electronic and Electrical Engineering (Tel. 0742-78555, Ext. 149) to whom one copy of a curriculum vitae should be sent. Quote ref. R 222/G.

8353(A)

UNIVERSITY OF NAIROBI—KENYA

Applications are invited for the post of

SENIOR LECTURER

in the
DEPARTMENT OF PHYSICS

Applicants should possess a Ph.D. in Physics and have considerable University teaching and research experience as evidenced by publications. Active fields of research in the Department are Theoretical and Solid State Physics, ionospheric physics, palaeomagnetism, and applied geophysics. Any experience in one of these areas would be an advantage.

Salary scale: K£2,988 to K£3,984 p.a. (K£1=£1.33 sterling). The British Government may supplement salary by £4,770 p.a. (sterling) for a married appointee or £3,252 p.a. (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowance and holiday visit passages. S.S.S.F. or F.S.S.U.; family passages; medical aid scheme; housing allowance; various allowances.

Detailed applications (2 copies) including a curriculum vitae and naming 3 referees should be sent by air mail not later than December 12, 1978 to the Registrar (Recruitment and Training), University of Nairobi, P.O. Box 30197, Nairobi, Kenya.

Applicants resident in U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

SALFORD AREA HEALTH AUTHORITY (TEACHING)
HOPE HOSPITAL
(University of Manchester School of Medicine)
Eccles Old Road
SALFORD M6 8HD

RESEARCH TECHNICIAN

required for the recently formed Department of Rheumatology. The job will involve the general running of the laboratory and assistance with research into inflammatory aspects of rheumatoid and other inflammatory conditions. Experience in tissue culture and/or immunological techniques would be preferred.

Salary will depend on qualifications and experience and it is hoped that the successful candidate will be appointed on the salary scale £3,261 rising to £4,680.

Application forms can be obtained from the Sector Administrator, telephone number 061-789 7373, Ext. 202 to whom they should be returned by November 27, 1978.

8328(A)

At Walton Oaks research is directed towards both animal disease and human metabolic disorders. The group concerned with the latter will relocate to our new site at Great Burgh (4 miles from Walton Oaks) in 1979. Within our multi-disciplinary project teams we now require:

PhD Chemists

Within three of our research teams opportunities exist to participate in the planning and execution of the synthetic organic chemistry programmes. Applications are invited from newly qualified PhD Chemists and from those with up to 2 years post-doctoral experience. B.Sc Chemists with a good honours degree (1st or 2(i)) and 3-5 years' relevant post graduate experience are also invited to apply.

B.Sc Biochemists

Two vacancies exist for graduates who within the last two years have achieved a good honours degree in biochemistry or physiology/biochemistry. The first position (for which HNC/D candidates with appropriate experience will also be considered) involves the primary and secondary screening of hypolipidaemic compounds. The person appointed to the second position will assist in the study of platelet function with respect to arterial thrombosis.

Post-Doctoral Biochemist for Diabetes Research

This is a senior position within a group studying maturity on set diabetes and the successful applicant is likely to have undertaken 2-3 years' post doctoral work in diabetes research or a closely related field. Applicants must be capable of initiating a research programme and of motivating the staff involved in its execution.

The men and women recruited to the above positions will enjoy excellent working conditions including flexible working hours.

Please submit full personal and career details (including current salary) to the following, or telephone for an application form:

Mrs M. R. Minchin,
Beecham Pharmaceuticals Research Division,
Walton Oaks, Dorking Road,
TADWORTH, SURREY
Tadworth 4444 (or 2444)

oxford polytechnic

Department of Construction

Technician – Geology

(£3,279 to £3,651 inclusive of all supplements)

Technician required in the Geology Section of the Department of Construction, whose duties will include special responsibility for curating the teaching collections.

Further particulars and application forms may be obtained from the Deputy Administrator, Oxford Polytechnic, Oxford OX3 0BP.

8290(A)

NEWCASTLE Area Health Authority (Teaching) Newcastle General Hospital, Senior non-medical Biochemist required for the Neurochemistry Department. The duties include specialised diagnostic procedures in neurology and research in neuromuscular disease. Candidates must possess a good honours degree, and a Ph.D. or suitable research experience—particularly in enzymology—would be an advantage. The appointment may be made at basic grade if the candidate considered most suitable has not yet had sufficient experience to warrant senior grading. Applications in own words, quoting names and addresses of two professional referees, to Western Sector Administrator, Newcastle General Hospital, Newcastle upon Tyne NE4 6BE, by November 24, 1978. Further details may be obtained from Dr R. J. T. Pennington, Department of Neurochemistry at the above address. Tel: (0632) 638811 Extn. 483. 8306(A)

RESEARCH TECHNICIAN

SCHOOL OF CHEMICAL AND PHYSICAL SCIENCES
Kingston Polytechnic

The technican will be required to work in collaboration with Dr A. G. Skinner on certain aspects of the chemistry of flame retardants used in synthetic polymers. The work, which is supported by the S.R.C., will be aimed at understanding the mechanisms of flame retardancy and will include polymer synthesis, testing and thermal decomposition studies. A knowledge of chemistry to degree or equivalent level is preferred.

The appointment is on a temporary basis, up to 2 years only, at T2 grade £3,564 inc.

Application forms, to be returned as soon as possible, from the Assistant Registrar (personnel), Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. 01-549 1366.

8356(A)

THE UNIVERSITY OF SHEFFIELD
RESEARCH FELLOW IN THEORETICAL CHEMISTRY

A vacancy occurs at postdoctoral level in a research group working on theories of the electronic structure and properties of molecules. Tenable immediately for one year with possible renewal. Salary in range £3,883 to £4,631 a year. Applicants, men or women, should have some experience (pre- or post-doctoral) in the field and should write directly to Professor R. McWeeny, Department of Chemistry, The University, Sheffield S3 7HF, with a curriculum vitae and the names of two referees. Quote ref. R 223/G. 8357(A)

PLYMOUTH POLYTECHNIC

School of Environmental Science

SL/LII MICROBIOLOGY

Salary scale:
£4,101 to £7,572

To contribute to the teaching of microbiology in the Biological Sciences degree (with special honours option in Microbiology) to H.N.D. and H.N.C. courses in Applied Biology and the M.Sc. degrees in Applied Fish Biology.

Preference will be given to candidates with experience in Virology.

LECTURER II ECOLOGY

Salary scale:
£4,101 to £6,558

Should be honours graduates in Biology or Environmental Sciences with a strong ecological background and a Ph.D. or equivalent research experience to take part in and organise undergraduate courses in Marine, Freshwater and/or Terrestrial Ecology. There will be opportunities to develop special teaching interests in honours degree options in Biological Sciences and Environmental Science and/or the Masters degree in Applied Fish Biology. Resarch in a suitable topic will be encouraged.

LECTURER II INORGANIC CHEMISTRY

Salary scale:
£4,101 to £6,558

Applicants should be suitably qualified with a broad knowledge of Inorganic Chemistry. Some specialisation in Analytical, Pollution or Marine Chemistry would be an advantage.

Application forms to be returned by **November 24, 1978** can be obtained with further particulars from the **Personnel Officer, Plymouth Polytechnic, Drake Circus, Plymouth PL4 8AA.**

work in the field of reproductive mmunology. Applicants should have perience in cellular immunology. he area being investigated comprises aternal cell-mediated immunity to tal and placental antigens in normal d abnormal human pregnancy.

Salary in range £3,883 to £5,604 epending on age. Grant support is r 3 years.

A curriculum vitae with the name d address of two referees should be nt by December 15, 1978, to Dr . W. G. Redman, John Radcliffe ospital, Headington, Oxford OX3 DU, from whom further information ay be obtained. 8266(A)

UNIVERSITY COLLEGE OF NORTH WALES BANGOR

Applications are invited for the post of
LECTURER IN BOTANY
in the College's School of Plant Biology.

The successful applicant will be expected to teach courses in plant morphology and anatomy and perhaps also ultra-structure, and will have the opportunity to develop new courses in areas of his/her special interests.

The appointment will be to the Universities' Lecturer Scale: £3,883 to £7,754 per annum.

Applications (two copies), giving details of qualifications and experience, together with the names and addresses of three referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further particulars may be obtained.

Closing date for applications: November 20, 1978. 8297(A)

Radio Astronomer

The National Institute for Telecommunications Research has several vacant positions at the Radio Astronomy Observatory, Hartebeesthoek, Republic of South Africa. The Observatory is active in a wide range of work covering astronomical research, development of electronic instrumentation for radio astronomy and the development of computer software for real time control of observing programmes and for data reduction.

The Observatory is situated 65 km north-west of Johannesburg and has a computer controlled 26-m radio telescope. Cryogenic receivers are available for 21, 18, 13 and 6 cm wavelengths. Additional equipment includes continuum radiometers, a digital correlation spectrometer and a Mark II c VLBI terminal. A mini computer is available for off line programme development and for data analysis.

Some experience in radio astronomy is desirable, and a background in spectral line work or in very long baseline interferometry would be a strong recommendation. However, applicants with a background in electronics and computer science would also be considered. Applicants with adequate experience would be considered for the position of Deputy Head of the Observatory.

For further information and the prescribed application form, please telephone London 01-242 1766. Alternatively, an application form may be obtained from THE OFFICE OF THE SCIENTIFIC COUNSELLOR, CHICHESTER HOUSE, 278 HIGH HOLBORN, LONDON WC1 7HE.

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF BOTANY

Applications are invited for a Lectureship in this Department from candidates with interests in Higher Plant Genetics. Within this field preference will be given to candidates with a particular interest in plant reproduction.

The salary will be in the range £3,883 to £7,754, but the initial appointment will be made in the range £3,883 to £4,383 per annum (interim scales).

Further particulars and forms of application, returnable not later than November 30, 1978, from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Ref No. 652. 8305(A)

UNIVERSITY OF NAIROBI—KENYA
Applications are invited for the following posts in the
DEPARTMENT OF AGRICULTURAL ECONOMICS
PROFESSOR

Applicants must possess a good honours degree in Agricultural Economics, Economics or Agriculture and a Ph.D. in Agricultural Economics. Relevant teaching and research experience are essential. Academic duties will mainly concern lecturing and research supervision of M.Sc. and Ph.D. students. The appointee will be responsible for further development of the undergraduate curriculum and organisation of M.Sc. research.

ASSOCIATE PROFESSOR

Applicants must possess a Ph.D. in Agricultural Economics or Economics. Candidates should have considerable experience in teaching and research as substantiated by published work. Specialisation in Agricultural marketing and/or marketing of Food products will be added advantages. Academic duties will mainly concern lecturing and research supervision of M.Sc. and Ph.D. level.

Salary scales: Professor K£4,632 to K£5,562 p.a., Associate Professor K£3,864 to K£4,488 p.a. (K£1=£1.33 sterling.) Family passages; S.S.S.F. or F.S.S.U.; medical aid scheme; subsidised housing/housing allowance; various allowances.

Detailed applications (2 copies) including curriculum vitae and naming 3 referees should be sent airmail to Registrar (Recruitment and Training), University of Nairobi, P.O. Box 30197, Nairobi, Kenya. Closing date: December 12, 1978.

Applicants resident in U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 8381(A)

UNIVERSITY OF SOUTH FLORIDA

CHAIRMAN OF THE MARINE SCIENCE DEPARTMENT

The Department of Marine Science of the University of South Florida located at St Petersburg announces the availability of the position of Chairman of the Department. Marine Science at USF has been designated by the Board of Regents of the State University System for special funding by the State Legislature for its development as a graduate Center of Excellence.

The Department now consists of ten faculty members. Six additional faculty members are being recruited. The Department's primary mission is research and graduate training.

The Chairman should be a Ph.D. with excellent research credentials and considerable administrative experience. A background of work in a marine station or oceanographic institute is highly desirable. The rank is Professor. Salary will depend on experience and professional accomplishment but the 12 month minimum is $35,000. The appointment can be made at any time during the academic year. The closing date for the receipt of applications is January 1, 1979.

Applicants should send complete résumés to Dr L. T. Hopkins, Chairman of Search Committee, Department of Marine Science, University of South Florida, St Petersburg, Florida 33701. The University is an affirmative action equal opportunity employer.

Advertisement for Chief Technician Post—Geology Department

A highly qualified technician is needed for the departmental laboratory workshop. The position involves routine processing of standard geological services (thin sections, core treatment, grain mounting, etc . . .) and organisation and supervision of the workshop. The successful candidate must possess basic knowledge in repair and maintenance of electrical laboratory appliances and instruments. A B.Sc. in geological or physical sciences is desirable. Strong command of the English language is essential. Send résumé to: **Chairman, Geology Department, Kuwait University, P.O. Box 5969, Kuwait.** 8335(A)

LINCOLN COLLEGE

(University College of Agriculture)

NEW ZEALAND

CHAIR IN HORTICULTURE

The Council of Lincoln College, University College of Agriculture, invites applications for the position of Professor of Horticulture and Head of the Department of Horticulture, Landscape and Parks. This Chair has become vacant on the appointment of Professor T. M. Morrison to the position of Director of the Queensland Agricultural College.

Applicants should hold an advanced degree in a field appropriate to any of the responsibilities of the Department which cover horticultural sciences, production, management, parks and recreation, and landscape architecture, and should have an established record in teaching and/or research.

The successful applicant will be appointed as Head of Department and will be responsible to the College Principal for the administration of his Department. Previous administrative experience will therefore be taken into consideration.

The appointment will be made within the existing range of professorial salaries, NZ$23,012 to NZ$29,188 per annum, the commencing salary being determined by the College Council. Academic salary scales are at present under review.

Expenses of appointment reimbursed up to specified limits. New Zealand Government Superannuation is available.

Further details and General Conditions of Appointment are obtainable from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the College.

Applications close on January 15, 1979. Please quote Vacancy No. 78/60. 8294(A)

CELL SURFACES

Applications are invited for a three-year postdoctoral position available from January 1, 1979 for research on animal lectins and cellular interactions. Salary £4,130 to £4,601.

Applications with names of two referees to Dr G. M. W. Cook, Department of Pharmacology, Hills Road, Cambridge CB2 2QD. 8365(A)

UNIVERSITY OF OXFORD

DEPARTMENT OF ZOOLOGY

Appointment of a

DEPARTMENTAL DEMONSTRATOR IN DEVELOPMENTAL BIOLOGY

Applications are invited for the post of Departmental Demonstrator in Developmental Biology. The person appointed would be expected to take up the post by October 1979. The successful candidate, who should recently have received a Degree of Doctor of Philosophy or be in his/her final year before submission, will be required to take part in developmental biology teaching and to undertake research in developmental biology.

The appointment will be for three years in the first instance with the possibility of renewal for a maximum of a further three years. The salary subject to review will be within University scale £3,384 per annum to £4,466 per annum with membership of U.S.S.

Applications, including the names of two referees, should be submitted to Head of Department, Department of Zoology, South Parks Road, Oxford OX1 3PS, by December 15.

8338(A)

FELLOWSHIPS

UNIVERSITY OF NEWCASTLE UPON TYNE FELLOWSHIPS

Applications are invited for the following Fellowships (tenable for two years from October 1, 1979) from persons who have shown themselves able to carry out original research. The value of each Felllowship is £3,883 in the first year and £4,133 in the second year (under review).

SIR JAMES KNOTT FELLOWSHIPS

TWO Fellowships available in any faculty.

WILFRED HALL FELLOWSHIP

ONE Fellowship available for research in the Faculty of Science.

EARL GREY MEMORIAL FELLOWSHIP

ONE Fellowship available for research in any faculty. As a general rule this Fellowship will be awarded to candidates who have graduated from the University of Newcastle upon Tyne.

Further particulars and application forms (which must be returned by December 31, 1978) may be obtained from the Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU. 8345(E)

UNIVERSITY OF WARWICK POSTDOCTORAL RESEARCH FELLOW

in Molecular Beam Scattering

Applications are invited for an SRC Postdoctoral Research Fellowship in the Department of Chemistry and Molecular Sciences to work on the investigation of simple ion molecule reactions using a crossed molecular beam apparatus in collaboration with Dr D. M. Hirst. Applicants should have experience in electronics, high vacuum work and preferably in molecular beams. The post, which is available immediately, will be for one year in the first instance, with the possibility of renewal for a further year. Salary on the Range 1A scale: £3,883 to £6,555 p.a. Application forms and further particulars from the Academic Registrar, University of Warwick, Coventry, CV4 7AL to whom applications should be returned as soon as possible. Please quote Ref. No: 14/3A/78. 8383(E)

EMBO

European

Molecular Biology Association

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1979 AWARDS

Next deadline: February 20, 1979

The long term fellowships will usually be for a period of up to one year but applications for a renewal for a second year are considered. To be eligible a candidate must hold a doctors degree. Preference will be given to European and Israeli applicants wishing to work within Europe or Israel. EMBO long term fellowships are NOT, however, awarded for exchanges between laboratories within any one country. Applications for fellowships to be held outside Europe and Israel are considered but they have a lower priority, as do applications from non-European scientists wishing to work in Europe or Israel.

The deadline for applications for the 60 fellowships to be awarded in April 1979 is February 20, 1979. Because the selection procedure involves an interview this deadline should be respected.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organisation, 69 Heidelberg 1, Postfach 1022.40, F.R. Germany. 8317(E)

UNIVERSITY OF ILLINOI

AT URBANA

Urbana, Illinois

HIGH-FIELD N.M.R. POSTDOCTORAL FELLOWSHIPS

Applications are invited fc postdoctoral work on the NMR c systems of chemical and biologic interest, under the direction c Professor Eric Oldfield. Fourie transform spectrometers equippe with widebore super-conductin magnets, operating at 360, 220 an 150 MHz, are available for use o the following projects:

1) Quadrupole-echo studies c specifically ^{2}H-labelled mebrane Topics of interest include the stud of protein-lipid interaction in th cytochrome oxidase system and re laxation studies in liquid crystals.

2) Phosphorus-31 NMR studie of protein-lipid interaction in mode and biological membrane systems

3) High-resolution ^{13}C NMI spectra of protein crystals usin high-power decoupling and magic angle sample-spinning techniques together with studies of protein structure in solution using large sample sideways-spinning tub probes.

4) Development of a LN$_2$ an then a LHe cooled-coil probe fo room temperature high resolutio NMR.

Applications, consisting of curriculum vitae, list of publica tions, and the names and addresse of three referees should be sent to

Professor Eric Oldfield
School of Chemical Sciences
University of Illinois at Urban
Urbana, IL 61801, U.S.A.

The University of Illinois is a Equal Opportunity / Affirmativ Action employer. 8291(E)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

GEOPHYSICS AND PLANETARY PHYSICS

Applications are invited for a POS DOCTORAL FELLOWSHIP RESEARCH FELLOWSHIP in sm friendly research group with w interests in theoretical global g dynamics and planetary physics: g physical fluid dynamics, planet magnetism, rotation, deformati Appointment will be for one year the first instance, renewable for second year. Send curriculum vi and names of three referees to P fessor M. G. Rochester, Physics D partment, Memorial University Newfoundland, St John's, Newfou land, Canada A1B 3X7.

8362(E)

UNIVERSITY OF SUSSEX

School of Biological Science

RESEARCH FELLOWSHIP IN BIOCHEMISTRY

Applications are invited for a postdoctoral Research Fellowship in Biochemistry to work on an M.R.C. financed project to investigate the mechanism and regulation of RNA synthesis during oogenesis in the amphibian Xenopus Laevis.

The appointment will be fo approximately two years commencing as soon as possible, at an initial salary in the range £3,88 to £6,555 per annum on the Research and Analogous Facult 1A scale, with superannuation benefits.

Applications, giving qualifications, experience and names o two referees, should be sent t Dr T. Beebee, School of Biological Sciences, University of Sussex Falmer, Brighton BN1 9QG.

8339(E)

FELLOWSHIPS

The Wellcome Trust

Wellcome Senior Research Fellowships in Clinical Science

The purpose of these Fellowships is to ensure that workers of high promise as clinical investigators are not deprived of opportunity by lack of an academic vacancy at the appropriate time. This fellowship scheme includes all medically qualified graduates from British universities in clinical and para-clinical departments working on a subject directly related to a clinical problem. Age limit 35 years. Salary according to age and experience within the range of £6,412 — £7,412 per annum (under review).

Wellcome Senior Research Fellowships in Basic Biomedical Science

The purpose of these Fellowships is to provide opportunities for research for medically or scientifically qualified scientists from British universities who have shown special promise in their initial studies of basic biomedical problems. Candidates must not be more than 32 years of age. Salary according to age and experience on a non-clinical scale £4,882 — £6,555.

Applications for both fellowship schemes, which are tenable for up to five years, must be held in an appropriate academic department in the UK, and have to be submitted by the Head of Department in which the candidate proposes to work. **Further details and application forms may be obtained from the Grants Section, The Wellcome Trust, 1 Park Square West, London NW1 4LJ. Tel: 01-486 4902. Completed application forms must be returned by 31st January 1979.** 8299(E)

STUDENTSHIPS

niversity of wales

niversity
ollege of
wansea

Postgraduate Studentships

Applications are invited for two ,R.C. **C.A.S.E. Studentships** in the **epartment of Physics**, one for esearch on the physics of the high oltage spark in conjunction with .E.G.B. Leatherhead, and the ther for an investigation of the hysical processes in pulsed neutron ounters in conjunction with .K.A.E.A. Winfrith.

Applicants should possess a good achelor's or Master's degree from British University in Physics, lectrical Engineering or related ubject, and will be encouraged to egister for a Ph.D. degree of the niversity of Wales.

Further details from Professor . Dutton. Telephone: (0792) 5678, Extn. 390. 8325(F)

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF METALLURGY
S.R.C./C.A.S.E. RESEARCH STUDENTSHIPS

Applications are invited from men and women for two Research Studentships.

(i) to study the influence of preferred orientation (texture) on the fatigue behaviour of steels used in heavy automotive applications (in collaboration with the GKN Group Technological Centre).

(ii) to examine void assessment in materials with changing structures during deformation in service (in collaboration with the Central Electricity Generating Board).

Value will be equal to that of a normal S.R.C. award increased by up to £500 per annum depending upon the experience of the successful applicants. It is expected that the holders of the studentships will register for a Ph.D. degree. Applications to Professor G. J. Davies, Department of Metallurgy, The University, Mappin Street, Sheffield S1 3JD by December 8, 1978. Quote ref: R 221/AI.

8341(F)

SYMPOSIA

INTERNATIONAL PEPTIDE SYMPOSIUM

The Intramural Program of the National Institute of Neurological and Communicative Disorders and Stroke will sponsor an International Symposium entitled "The Role of Peptides in Neuronal Function" to be held May 7 to 9, 1979 at the National Institutes of Health reservation in Bethesda, Maryland. The three-day meeting will draw together investigators from diverse disciplines for a comprehensive review of peptide research as it relates to the field of neurobiology.

The first day will include presentations on the anatomy and physiology of peptidergic neurons, as well as the synthesis and secretion of peptides. The second day will begin with a discussion of peptide-mediated communication in the nervous system, followed by reviews of the neurobiology of specific peptides, including angiotensin, neurotensin, somatostatin, substance P, vasoactive intestinal peptide, luteinizing hormone releasing hormone, thyrotropin releasing hormone, olfactory system peptide, bag cell hormone and neurodepressing hormone. The final day will be devoted entirely to the pharmacology, physiology and potential clinical application of opioid peptides.

The Symposium is being organised by Drs Jeffery Barker and Thomas Smith of the N.I.N.C.D.S. Laboratory of Neurophysiology. Those interested in attending should contact either Dr Barker and Dr Smith, Bldg. 36, Room 2C02, National Institutes of Health, 9000 Rockville Pike, Bethesda, Md. 20014. Tel: 301-496-2414.

8307(M)

ASSOCIATESHIPS

HERIOT-WATT UNIVERSITY
DEPARTMENT OF PHYSICS
POSTDOCTORAL RESEARCH ASSOCIATESHIP
S.R.C. C.A.S.E. STUDENTSHIP

Applications are invited from suitably qualified physicists or chemists to join an established group to work in the area of high power laser induced energy transfer processes in molecules, particularly relevant to laser induced isotope separation, photochemistry, and optically pumped molecular lasers.

The postdoctoral appointee should possess a Ph.D. and have experience in infra-red laser physics or molecular spectroscopy.

The salary would be up to £4,382 per annum (under review) and the appointment would be for two years in the first instance.

The C.A.S.E. studentship will be for a period of three years, and the appointee will research for a Ph.D. and should possess a degree in either physics or chemistry.

Applicants should contact Dr C. Pidgeon, Physics Department, Heriot-Watt University, Riccarton, Edinburgh (Tel: 031-449 5111, Ext: 2333) as soon as possible to obtain further information. 8340(O)

APPOINTMENTS VACANT

POSTDOCTORAL POSITIONS

Two positions available immediately d for next summer for Biochemical d Biophysical studies on the regulan and mechanisms of gene expression d the nucleic acid-protein interion. Experience in molecular logy or physical biochemistry irable.

Interested applicants should send rriculum vitae and three letters of ommendation to Dr C.-W. Wu, partment of Biochemistry, Albert stein College of Medicine, Building **205, Bronx, N.Y. 10461. An equal portunity employer.** 8336(A)

UNIVERSITY COLLEGE DUBLIN

Applications are invited by the Governing Body of the College for the following full-time statutory post:

PROFESSORSHIP OF EXPERIMENTAL PHYSICS

Prior to applications, further information (including details of application procedure) should be obtained from Mr J. P. MacHale, Secretary and Bursar, University College, Dublin 4. Tel. 693244, ext. 431.

THE LATEST DATE FOR RECEIPT OF COMPLETED APPLICATIONS IS THURSDAY DECEMBER 7, 1978. 8199(A)

POSTDOCTORAL RESEARCH ASSOCIATESHIPS AT THE NAVAL MEDICAL RESEARCH INSTITUTE BETHESDA, MARYLAND

Sponsored by
The Naval Medical Research and Development Command
in association with
The National Research Council

Competitive applications are now being accepted for postdoctoral research associateships, starting October 1, 1979, in the areas of behavioural sciences, environmental stress, immunology, microbiology, parasitology, pathology, toxicology, and underwater bimedical research. Candidates must have received their doctoral degree (M.D., Ph.D., D.V.M. or Sc.D.) within the last five years. Salary will be $19,263 per annum.

Completed application forms are due not later than January 15, 1979. Information and application forms may be obtained by writing to the National Research Council Associateship Office (JH608-N3), 2102 Constitution Avenue, N.W., Washington, D.C. 20418. An Equal Opportunity Employer.

8318(O)

ASSISTANTSHIPS

UNIVERSITY COLLEGE, GALWAY, IRELAND
RESEARCH ASSISTANTSHIPS (2)

University College, Galway, announces two postgraduate student research assistantships tenable in the Department of Physics and/or the Department of Oceanography for participation in a field and laboratory study of oceanic whitecaps, sea spray, and their influence on the marine atmosphere. Preference will be given to students wishing to pursue dissertation or thesis research on these topics.

These assistantships are available for the present academic year. Salary: £1,500 per annum.

Letters of application, with academic transcripts and the names of two references, should be in the hands of Dr E. Monahan, Department of Oceanography, U.C.G., within two weeks of the date of this advertisement. Successful applicants will be expected to take up their assistantships *not later than 1 January, 1978.* 8374(P)

DEPARTMENT OF PHYSIOLOGY

UNIVERSITY OF BRISTOL
RESEARCH ASSISTANT

Applications are invited for a Postdoctoral Research Assistantship within the Department of Physiology, University of Bristol, for a period of one year in the first inctance, renewable-up to three years. Salary on the scale £3,883 to £4,882 per annum.

The post may be taken up in one of a number of laboratories where the research programmes are concerned with the following topics, muscle spindles, trigeminal pain, developmental neurobiology, simple nervous systems, or flagellar mobility. Many of the research problems involve the use of structural methods as well as or instead of electrophysiological methods. Enquiries may be made to Professor T. J. Biscoe, at the Department of Physiology, University of Bristol, Medical School, University Walk, Bristol BS8 1TD.

Detailed applications, including the names and addresses of three referees should be sent by November 22, to the Registrar and Secretary, University of Bristol, Senate House, Bristol BS8 1TH. 8346(P)

UNIVERSITY OF BRISTOL

DEPARTMENT OF PHARMACOLOGY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a postdoctoral research assistantship funded by The Wellcome Trust for three years from the date of appointment. The project is an investigation of the neuronal basis of stimulus evoked analgesia using electrophysiological techniques. Previous experience of electrophysiological recording from the C.N.S. or peripheral sensory electrophysiology is desirable.

Salary will be on the appropriate academic scales, determined by age and experience (minimum £4,382 p.a. at age 26—scale under review). Applications giving details of age, qualifications and experience, together with the names of two referees, should be sent by November 17 to Dr R. G. Hill, The Medical School, University Walk, Bristol BS8 1TD.

8347(P)

STUDENTSHIPS

UNIVERSITY OF LEICESTER

DEPARTMENT OF PHYSICS

THE PHYSICS OF DISORDERED MATTER
S.R.C. C.A.S.E. STUDENTSHIP

Applications are invited for a C.A.S.E. research studentship with the Department of Physics leading to the degree of Ph.D. The project is a study of liquid semiconductors and alloys using photoelectron spectroscopy and will be undertaken in collaboration with A.E.R.E. Harwell. It provides an opportunity to join an active research group working in a research area of particular relevance to modern technology in which much fundamental physics remains to be discovered.

Applications, which should give the names of two persons to whom reference may be made, are sent to Dr C. Norris, Department of Physics, The University, Leicester LE1 7RH.

8321(F)

COURSES

EMBO LABORATORY COURSE
on
"PLASMIDS—A COURSE IN ADVANCED TECHNIQUES"

APRIL 9 to 29, 1979
University of Erlangen, Germany
Organisers: Kenneth Timmis and Alf Pühler

The course will consist of laboratory experiments and lectures designed to instruct participants in the use of recently developed methods that are particularly important for the genetic, structural and functional analysis of plasmid genomes. These will include transposition mutagenesis, gene cloning, the uses of restriction enzymes, electron microscopy and DNA sequencing for structural analysis, and the uses of minicell and *in vitro* systems for studying plasmid expression and replication.

A mini-symposium on the theme "Plasmids of Medical, Environmental and Commercial Importance" will follow the laboratory course.

Applications, with a short curriculum vitae including future scientific interests, and any information which might help in their evaluation should be sent in duplicate to :

Professor A. Pühler
Institute of Microbiology and Biochemistry
University of Erlangen
Friedrichstr. 33
D 8520 Erlangen, FRG

8376(D)

European Molecular Biology Association
EMBO COURSE
ION-SENSITIVE INTRACELLULAR MICROELECTRODES

Bristol, England,
June 25 to July 8, 1979

The course is for 12 active researchers who wish to learn how to use ion-sensitive intracellular microelectrodes. Participants will be taught how to make, calibrate and do experiments with K^+, Cl^-, Na^+ and pH^+-sensitive microelectrodes. Most of their time will be spent in the laboratory, although there will be some lectures during the course and a two-day round-table discussion at the end. During the round-table, a number of leading workers in the field will describe their methods and recent results. Instructors will include Roger Thomas, Dave Ellis, Richard Vaughan-Jones, Jochen Deitmer, Bill Moody and Andrew Sharp.

Applicants should have some experience of electrophysiological techniques, and have a convincing reason for wishing to take the course and a letter of recommendation.

Acceptance for course will be notified to applicants early in March. Participants will have to pay their own accommodation and subsistence expenses (estimated at about £100), their travel expenses and a Course Registration Fee of £30. One or two grants are available for applicants who can pay only their travel expenses. Accommodation will be arranged by the course organiser.

Applications to Dr R. C. Thomas, Department of Physiology, University of Bristol, Bristol BS8 1TD, England, must be received by February 19, 1979.

8322(D)

APPOINTMENTS VACANT

MARINE BIOLOGICAL ASSOCIATION OF THE UNITED KINGDOM
SCIENTIFIC OFFICER

A Scientific Officer is required at the Plymouth Laboratory to help with current research on cephalopods and marine worms. The successful applicant will have a good degree in Zoology and a keen interest in systematics, morphology and marine ecology. Duties will include many routine tasks and some heavy manual work, particularly during cruises. Salary is on the scale £2,839 to £4,415 per annum. There is a non-contributory Pension Scheme. Applications with full curriculum vitae and giving the names of at least two referees, should be sent to The Director, Marine Biological Association of the United Kingdom, The Laboratory, Citadel Hill, Plymouth PL1 2PB, to arrive not later than December 1, 1978.

Steady-State Enzyme Kinetics

Stanley Ainsworth

Identifies the basic ideas of the subject for the graduate and advanced undergraduate student, and familiarises the reader with them so that they may then be applied to any problem likely to be encountered. Although it cannot altogether avoid mathematical presentation, almost all the equations used require only an elementary acquaintance with algebraic manipulation. Moreover the arguments themselves are presented as fully as possible to enable the reader to progress easily from each stage to the next.

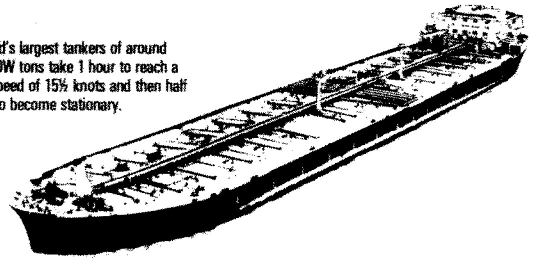
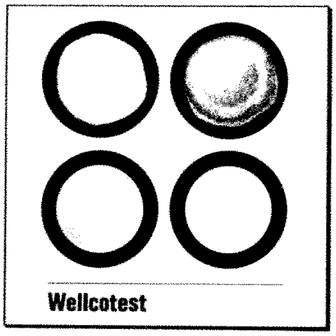
Circle No. 02 on Reader Enquiry Card.



The world's largest tankers of around 500,000 DW tons take 1 hour to reach a service speed of 15½ knots and then half an hour to become stationary.

A typical modern ocean-going tug, gross tonnage 2,500. Time to dead halt from maximum speed of 15 knots is 40 seconds.

The ESR test. Takes at least one hour to perform. Responds slowly in the monitoring of pathological conditions and drug therapy.



The CRP-Wellcotest. Two minutes latex test.

Like Erythrocyte Sedimentation Rate, CRP estimations detect the existence and degree of inflammation, and assess various combative therapies.

Like ESR, CRP parallels and indicates the extent of inflammation and tissue necrosis, especially in patients with rheumatoid arthritis, acute and chronic bacterial infections, myocardial infarctions and in post-operative conditions.

Unlike ESR (or blood leucocyte counts or body temperature checks), CRP is an extremely fast indicator. It rises and returns to normal more rapidly in response to disease process and drug therapy.

Unlike "ESR which depends on several variables, CRP is a discrete entity . . ." *1*

1 Brit. med. J. (1977) Volume 1, 22nd January.

CRP-Wellcotest requires no heat inactivation, no sample dilution, comes as a *complete* kit, has a removable reagent tray to save refrigeration space and *it does not prozone.*

Agglutination with CRP-Wellcotest indicates a positive result with a serum CRP level greater than 0.6 mg/100 ml. Semi-quantitative results may also be obtained by serial dilution.

CRP-WELLCOTEST*
–faster indicator than ESR

Find out why more researchers use S&S membranes for RNA/DNA hybridization, protein binding, DNA sequencing, and DNA blotting.

It won its reputation as B6, its old name. Now its catalog number is BA 85. They're two numbers for the same S&S nitrocellulose 0.45μm membranes. Either way, more researchers use S&S 0.45μm membranes than any other brand, in circles for adsorption of DNA strands and in sheets to blot DNA fragments from gels. As the laboratory standard, S&S is specified and preferred in most of the papers published on RNA/DNA hybridization, protein binding assays, or RNA or DNA sequencing.

If you don't know why, it's easy to find out. Fill in and mail the coupon to S&S, and receive a free sample of S&S BA 85—a 15cm square or circles up to 50mm diameter.

Frog oocyte

How to highlight intermediate and final results.

If you are involved in precise compound formulation, take a close look at a Mettler PC balance with GC301 Application Input Device. With this combination, you can perform "Ad" weighings, weigh in from zero, recall an intermediate total and, at the end, record the total weight – with or without the tare.

Even if you are completely absorbed in your work, a glance at the digital display of the PC balance gives you clear and unmistakable weight information.
In addition, with the *Mettler DeltaRange* you can weigh in with an accuracy of 0.001 g (PC440) or 0.01 g (PC4400).

So, if you want to keep an eye on intermediate and final results, keep in mind the PC/GC301 combination. It will save you time and money.

Mettler

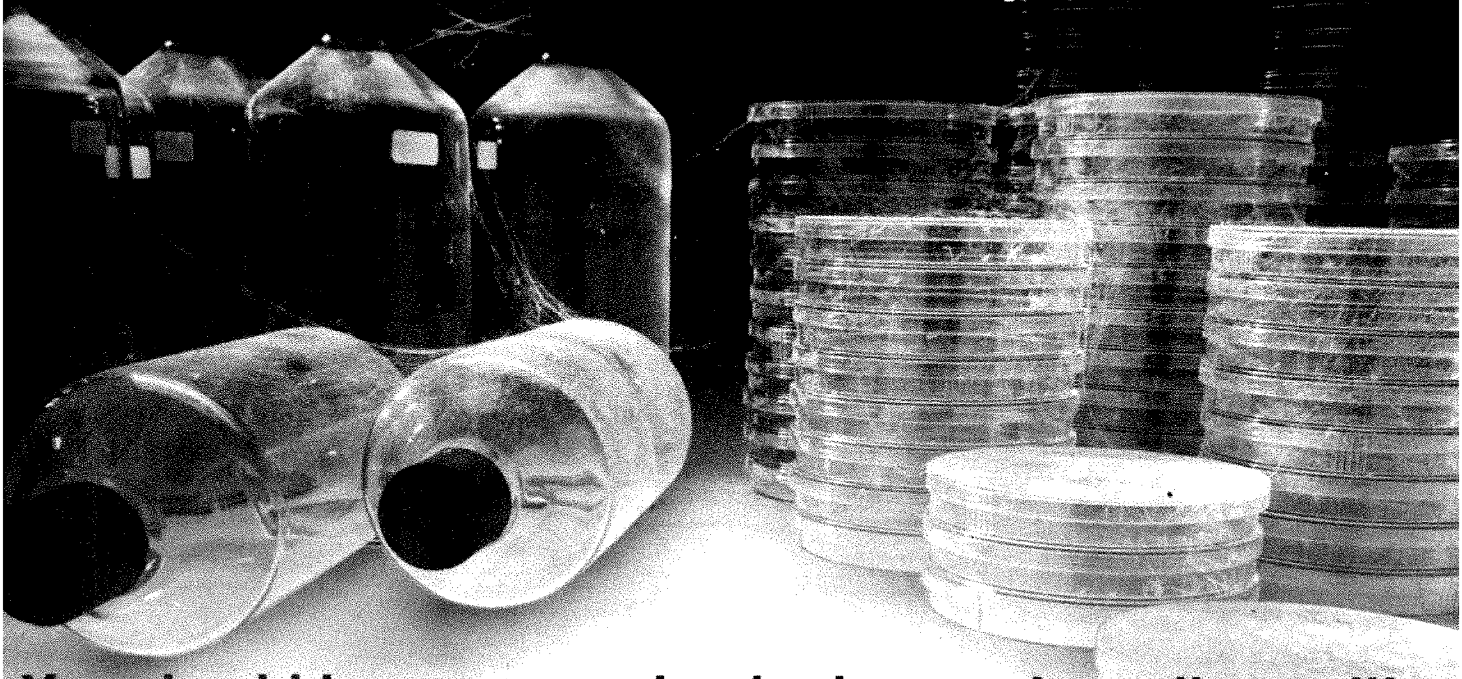
Culturing cells?

Would you like a cell culture technique
which gives you higher cell yields for less effort,
less time and less money?



You should know more about microcarrier culture with

Cytodex™ 1

- High cell yields
- Much smaller working volumes
- Easy control and monitoring of cultures
- Simple harvesting of cells without centrifugation
- Saves you space, effort, time and money

One gram of Cytodex 1 gives you the same capacity
for cell growth as 7 roller bottles or 76 standard Petri dishes.

Cytodex™ 1 - the new dimension in cell culture.

Guide to authors

- ● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- ● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- ● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- ● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, v, 11 Nov. (1976).

ot just an instrument... a totally new u Pont LC system.

Du Pont's new high-performance Model 850 gives you full visual display, instant adjustment, all the versatility, reliability and speed you want.

This new Du Pont LC system es the operator immediate call-out owledge of all key operating para- eters and the ability to change those rameters while the system is nning.

Other features of the Du Pont 0 include

- precision constant-volume -piston pump
- microprocessor control of components
- immediate operator access while system is running
- built-in computerised diagnostics
- automatic gradient programming.

The new Du Pont 850 LC is designed to meet the demanding requirements of the research scientist as well as the special needs of the quality control analyst. The chromatographer is in total charge-with authority to change vital parameters without interrupting data reporting.

Nobel Prizes should give encouragement

WITH this year's Nobel Prizes awarded, it may be appropriate now to ask whether there is new ground to be broken in the future by changes in criteria applied to selection for the prizes reflecting changes in the nature of scientific enquiry itself and its relationship to society. Certainly in recent years there has been a cautious and belated recognition of astronomy as a subject appropriate for the physics prize. But there still remain large areas of scientific endeavour yet to be included within the orbit of the prizes, of which the earth sciences is perhaps the most conspicuous example. Within the present terms of award of the prizes these areas are unlikely ever to be recognised by the prize committees.

Many would argue that the prizes ought in any case to be phased out as they represent an outdated reward system, generate a fair amount of bitterness and jealousy, and often convey a spurious air of authority by their award that is misinterpreted not just by the general public but even by the scientists themselves, who should know better. If the prizes are simply seen as the final often belated stamp of approval on a fine piece of work, then these arguments have considerable force. But they surely could be, and (with the exception of the peace prize) rarely are, a way of saying "this activity looks interesting. By awarding it a prize we will be giving it encouragement and will be drawing the attention of a much wider public to it."

It goes without saying that such an approach is much more risky. The work in question may end up in disappointment, and the publicity afforded to it may have been damaging. And much excellent work which at present leads ultimately to the award of a prize will fail to be recognised at the time. But it may well be that an aura of infallibility around the Nobel Prizes could be dispensed with.

As it happens, 1979 would be a particularly appropriate year for the prize committee to explore a new approach. Whatever the expected shortcomings of the United Nations Conference on Science and Technology for Development in Vienna next August, none but the most blinkered will by then be ignorant of the questions being raised about science in and for the developing world. One of the more frequently heard complaints by those involved in scientific work in the developing world is that the seductive attractions of a western-style academic science are too great for too many of the most highly intelligent, who abandon to less competent people the much more immediately relevant problems lacking reward-studded lustre. Nobel Prizes have been one of the ways of conferring this lustre. What could be more appropriate than that in 1979 a serious effort was made to identify work being done in the Third World of wide impact, even if not of exalted scholarship, and give to it an imaginative dose of encouragement. ☐

Victims of censorship

EVERY week roughly 20,000 copies of *Nature* go into the mail. Of these, rather more than 80% leave the United Kingdom for all parts of the globe from China to Peru. As far as we can tell they all reach their destination (barring the odd few that go astray), with one major exception. Certain countries in Eastern Europe take it upon themselves to censor the incoming mail of their citizens.

The pattern is not uniform; some countries don't bother, others are ruthless. By far the biggest offender is the Soviet Union. When there is any mention of that country in our news pages, whether it is favourable, neutral or critical, copies of that particular issue are often simply thrown away at the border. As a result our Soviet readers see, at best, half of all issues of the journal.

There are ways to try to beat the system, of course, but they are only marginally effective and temporary expedients. What is needed, and what is most unlikely to occur, is for governments given to these extraordinary petty gestures to recognise first that all intelligent scientists in their country know perfectly well much of what they are trying to suppress, and second that one of the most effective ways of crippling the growth of science is to inhibit the free flow of scientific literature. ☐

Funding delays handicap ISABELLE in race for new particle

The US Department of Energy has extended construction time for Brookhaven's 400 × 400 GeV accelerator from five to seven years. **David Dickson** reports on the implications.

PHYSICISTS at the Brookhaven National Laboratory on New York's Long Island are trying to persuade the Department of Energy to reverse its decision to extend the construction period of its new 400 x 400 GeV intersecting storage accelerator (ISABELLE).

At stake is a race with the European Organisation for Nuclear Research (CERN) in Geneva to demonstrate the existence of the theoretically predicted intermediate vector boson, known as the W particle. According to the Weinberg-Salam unification theory, this particle carries the weak force in the same way that the photon carries the electromagnetic force.

Initially, Brookhaven's scientists hoped ISABELLE's larger number of interactions would compensate for CERN's planned earlier start in the search for the particle using proton-antiproton interactions. The extra two years' delay in construction could, it is feared, considerably reduce chances of being first past the post.

Construction work on what has been described as the largest basic research project ever built began last month. When completed, the 2½-mile circumference accelerator will provide a range of detection facilities for studying the results of collisions between two beams of opposite circulating protons.

The Department of Energy, under pressure from members of Congress, agreed last year to put $23 million to begin construction work on ISABELLE into its budget request for 1979; when this money officially became available last month, a ground-breaking ceremony took place.

However, in an attempt to keep the lid on funding for high energy physics over the next few years, the department later announced that the accelerator's construction schedule would be increased from five years to seven. The first experiments have been pushed back from 1984 to 1986.

ISABELLE has been designed to make use of pulses of 30 GeV protons from the Alternating Gradient Synchroton, Brookhaven's last major high energy physics facility which came into operation in 1961. The pulses will be stacked sequentially in each ring until 10 amps of circulating current has been built up, at which time the two beams can be slowly accelerated to full energy and made to interact at six separate experimental stations.

The proton collisions will provide a centre-of-mass energy of 800 GeV, equivalent to that available from protons of 340,000 GeV striking protons at rest. ISABELLE will therefore be able to extend by a factor of 10 the centre-of-mass energy range presently available on CERN's Intersecting Storage Ring; it will also have a far greater luminosity (the factor which determines the number of interactions).

ISABELLE has been on the drawing board since 1971, when preliminary designs were first made, and has enjoyed the consistent backing of the US high energy physics community. Official procrastination was broken last year by Representative Jerome Ambro, a Long Island congressman with one eye on science and the other on the jobs and money ISABELLE will bring.

After some political horse-trading that also involved the decision to site the Solar Energy Research Institute in Denver, Colorado, Mr Ambro persuaded Congress to add $5 million to the Department of Energy's authorisation for 1978 to go ahead with ISABELLE—and to defeat attempts by the Office of Management and Budget to have the money deferred.

Further problems were raised when Dr Robert R. Wilson, director of Fermilab, tried to outbid Brookhaven for a major share of the 1979 budget in order to speed up the construction of Fermilab's Energy Doubler. However Wilson's hand was weakened when the department's High Energy Physics Advisory Panel reconfirmed top priority for ISABELLE.

The final hurdle came late in the spring, when the department announced that it had decided to maintain funding for high energy physics at a constant level over the next few years—and that ISABELLE's construction period was to be extended to avoid initial "peaking" that would upset this scheme.

In political terms, the department hopes this will make the high energy physics programme more acceptable to a cost-conscious Congress. However, economically, the result has been to increase the projected overall cost of ISABELLE from $240 million to $275 million; and scientifically it means the extra two-year delay until the first results are produced.

"We would not have built this machine just to discover the W particle," Dr Jim Sandford, project manager for ISABELLE said last week. He points out, for example, that the increased luminosity over CERN's SPS ring, means that Brookhaven will be in a much better position for a detailed analysis of higher energy states, decay modes and so on.

"But I do not want to miss out, if at all possible, in finding it. With our greater luminosity, we had a good chance of finding the particle ahead of CERN on the five-year schedule. On a seven-year schedule, we have considerably less chance."

Brookhaven scientists still hope that, once construction of the accelerator's superconducting magnets and other components is well under way, the Department of Energy can be persuaded to alter its policy and make more money available earlier—saving on costs by reducing labour and avoiding some of the effects of inflation.

So far, the department has remained firm. It has proposed to make available $45 million for ISABELLE's construction costs in the fiscal year 1980, making the total for the first two years still considerably less than the $80 million which the laboratory had proposed for the first year of construction alone. □

ESF warns of dangers of shortfall in posts for young scientists

"THERE is a potentially dangerous situation in Europe which is causing young scientists who might otherwise choose a career in research not to do so," Sir Brian Flowers, president of the European Science Foundation (ESF), said last week. He was speaking after the ESF assembly had approved the annual report for 1978.

A recent ESF study has shown that in most of its members' countries, "the majority of those now in employment will stay in office until the beginning of the 1990s when they will reach their normal retirement age. The demand for replacements during the next 15 years will be exceedingly low." The annual report says available posts are now so few that the chance of a junior research assistant getting a permanent university appointment has gone down from 70% in the 1960s to 15% this decade.

The problem of making posts available to young research workers is well-known. The ESF draft report adds one extra argument. In the past, it says, 65% of a university's budget was spent on personnel and the remaining 35% on maintenance, administration, upkeep of the library and research. Now the share taken by salaries has increased, leaving less for the other activities including research.

The ESF does not suggest what should be done. For the present it merely points out the dangers and urges countries to find their own solution.

The assembly approved a budget of 3.996m French francs for 1979. Among the activities it will finance are three new ones, two in the humanities—Byzantine and Chinese studies—and one covering the ESF's work in synchrotron radiation.

Ten member organisations are providing an additional 500,000 French francs for a feasibility study on building a European Synchrotron Radiation Facility. Such a machine would be distinguished from existing machines by its very high brightness, specially designed elements for each wavelength range, undulators which are very bright emitters and a beam time structure for time resolved studies. ESF hopes to complete its report within a year so a quick decision can be made whether to build the facility.

At the meeting of the Assembly, Sir Brian welcomed Dr John Goormaghtigh who takes over as Secretary-General from Dr F. Schneider in January 1980. Dr Goormaghtigh works in the social sciences. **Judy Redfearn**

Wiesner attacks increasing government regulation of US university research

INCREASING attempts to regulate university research have led to floundering relationships between the federal government and the academic community that have reached a "point of crisis", according to Dr Jerome B. Wiesner, science adviser to President Kennedy and now president of the Massachusetts Institute of Technology.

Speaking at a conference of research administrators in Washington last week, Dr Wiesner said that this could seriously curtail the effectiveness of the nation's major research universities, and that the increasing intrusion of the federal government into university affairs threatened their capacity to produce innovative ideas.

He singled out for particular attack proposals published earlier this year by the Office of Management and Budget to introduce significant changes in the accounting procedures—currently listed in the so-called Circular 21—by which universities compute how much they should be reimbursed for the direct and indirect costs of carrying out federally-sponsored research projects.

OMB has claimed that the revisions are aimed at rationalising the procedures used by different government agencies, and reducing the risks of the possible misuse of funds. Dr Wiesner, however, said that the proposed changes, which have been widely criticised by the research community, would weaken universities as institutions and reduce their capacity to conduct high quality research.

"There is no question, for example, that they limit in a destructive way reimbursement for indirect costs that are necessary and essential. There is no question that a number of the proposals are inequitable or administratively impracticable or both."

He called on President Carter to defer implementation of the revisions until a full study of the current problems faced by university research workers had been completed. "The proposed revisions to A-21 not only sacrifice flexibility but, far more significantly, they move in the direction of viewing universities in the same manner as commercial organisations and away from the concept of a partnership between the universities and the federal government."

Dr Weisner also criticised the recent decision of Congress, in passing the National Science Foundation's budget for the fiscal year 1979, to place a ceiling of $48,000—the maximum rate payable to Government scientists—on the salaries of university research scientists receiving university support.

"What this means is that Congress is limiting the reimbursability of salaries of the best faculty, the stars, the Nobel Prize winners, those people who make our institutions great. Universities will have to make up the difference, starting with an already substantial impact, and that's only the beginning," he said.

David Dickson

Few surprises in UNCSTD draft plan of action

A DRAFT plan of action has been published by the secretariat of the United Nations Conference on Science and Technology for Development (UNCSTD), scheduled to take place in Vienna next August. The plan will be discussed by the UN General Assembly in New York next week, and a revised version will then be considered by the conference's preparatory committee when it meets at the beginning of next year.

There are few surprises in the draft plan, which is essentially a synthesis of the various proposals made in the national and regional papers which have already been submitteed to the secretariat (a number of countries—perhaps most noticeably the United States—have yet to complete their national papers).

The draft plan of action has reduced the proposals to 201 separate recommendations grouped into two main sections: science and technology for development, and "institutional arrangements and new forms of international co-operation in the application of science and technology."

Popular themes include the need for codes of conduct covering both the transfer of technology and the behaviour of multinational companies, the need to improve scientific and technological information services and policy-making machineries, and concern about the effect of the "brain-drain" to developed countries. There are also suggestions for encouraging cooperation in research between developing countries, and ways of re-orienting educational systems towards national needs; and several countries ask for an emphasis on the development of appropriate technologies.

Other suggestions range from the proposal that developed countries set aside 0.5% of their gross national product for research related to Third World issues, to the suggestion that

0028–0836/78/0276—0201$01.00

regional "multinational" companies be set up to break the monopoly of foreign transnationals in selected areas of interest to a particular region—something that could be achieved, it is suggested, by polling the resources of a group of countries in the region and by arrangements for market-sharing, as is now done by the Andean pact countries of South America.

The draft plan says little about basic science. One of the few explicit references is in paragraph 63, which says: "One developing country and one market economy country recommend the fostering of basic research as an important basis for indigenous scientific and technological development." But the same paragraph continues: "Several countries recommend a more utilitarian rather than an academic approach to the results of scientific research and underline the special importance of applied research and technological development for countries with limited resources."

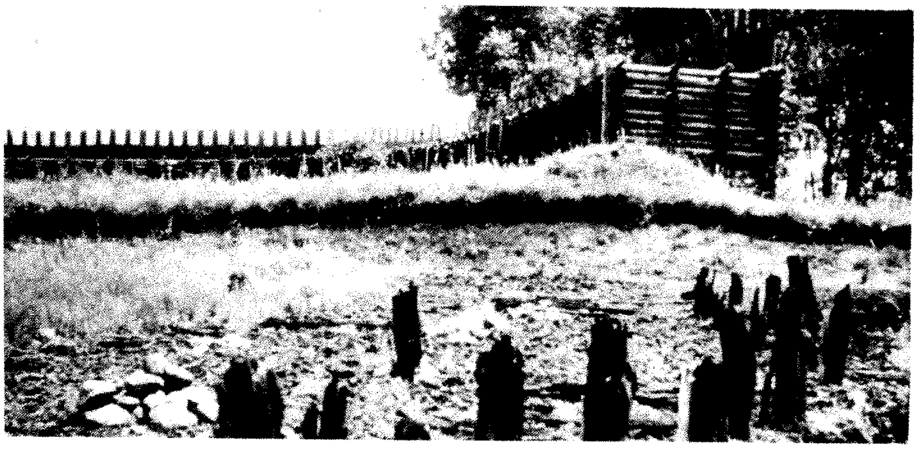
Nor is much attention given to the obstacles to applying science and technology to development although they had been stressed previously by the conference secretariat. The introduction to the plan of action admits that "the approach by most governments in the preparation of their national papers has been to deal implicitly with obstacles throughout their papers."

As a result, the secretary-general of the conference, Dr Frank Joao de Costa, says that he has adopted the same approach in the outline of the plan of action; and the introduction states that the number of obstacles treated explicitly "has necessarily been limited."

The two resulting paragraphs are vague and generalised. The first says merely that "systematic analysis and study" of such obstacles is a prerequisite for their elimination. And the second, in language somewhat typical of the whole document, states. "Many developing countries consider that the absence of an awareness of science and technology, often in the context of the social structure, cultural heritage, value system and religious traditions of a country may constitute an important obstacle to the application of science and technology."

David Dickson

Problems of preserving a 2,500-year-old township



Reconstruction of the palisade with original wood in the foreground. Below: applying the solution.

SINCE its discovery in 1933, Biskupin has posed a considerable problem to Polish archaeologists: how to excavate this prehistoric township whose timbers were preserved virtually intact in the peat without the immediate deterioration and decomposition of the finds once they are in contact with the air. A conference of wood conservation specialists, organised last September by the Polish State Archaeological Museum, which is responsible for conservation work at Biskupin, indicated, however, that during the last three years extremely satisfactory results have been attained at attempts at conservation *in situ*.

Biskupin, which dates from circa 550 B.C., was an island settlement of two-bedroomed wooden houses, arranged rectilinearly and enclosed by a palisade. Abandoned when the water-level of the lake rose, the houses collapsed and their timbers were preserved in the peat. The value of such a site for early iron-age archaeology is inestimable; however, until recently the problems of conserving the timber finds seemed insurmountable.

The new conservation programme at Biskupin uses a polyphenol resin to preserve the timber. The method is adapted from one introduced six years ago by Yurii Vikhrov, of Minsk, (Byelorussian SSR). In the Polish method the fluid is applied with a brush, and then cured by sunlight, temperature or catalyst hardening. Curing time depends on the conditions, but, using hot-air blowers, a typical figure would be 30 hours at 100 °C.

The resin penetrates the wood to a depth of 3 cm; this gives a mechanical strength that is quite sufficient for conservation; indeed, this method has already been used for the conservation of a whole mediaeval house at Brest-on-Bug. According to Teresa Stanczuk-Rozycka, head of the conservation laboratory of the State Archaeological Museum, the method, although expensive, nevertheless works out at only 20% of the cost of the method used in Sweden to conserve the timbers of the *Vasa*, and, unlike the Swedish method, is suitable for work *in situ*. Mrs Stanczuk-Rozycka further said that the September conference showed that the overall results of the method were extremely good, and that the programme of conservation would go forward.

At present, the conservation teams propose to work only on the remains of the gate and ramparts, excavated during the early digs, which are now under the greatest risk. With all future excavations, however, running conservation of the wood in parallel to the actual digging work will be carried out as a matter of routine.

And, since the actual technique of applying the fluid and, if necessary, the hot air blowers, is extremely simple, a large team of skilled conservationists will not be necessary. "Anyone can do it", Mrs Stanczuk-Rozycka, told *Nature*, "for example, students!"

Vietnam's scientists wait for books and equipment

AT THE HEIGHT of the Vietnam War, US Air Force chief General Curtis Lemay threatened to bomb North Vietnam "back into the Stone Age". Although American bombing never achieved this objective, it nonetheless destroyed a great many buildings, among them — factories, offices, hospitals and research laboratories. Today, in spite of extensive rebuilding office space is generally in very short supply, which means many scientists have to work in cramped conditions, particularly in Hanoi. In Ho Chi Minh City (formerly Saigon), things are not a great deal better, although it did emerge from the war less scarred.

Many of Vietnam's leading scientists have now moved to Ho Chi Minh City, under the auspices of the country's largest research establishment, the Vietnam Scientific Research Centre Laboratories of experimental biology, petrochemistry, and physics and chemistry of natural products are already established in the city. The latest addition is to be a laboratory of biochemistry and food chemistry, early next year.

One incentive for moving south is the prospect of working in some of the better-equipped food and pharmaceutical industries The great drawback is a shortage of scientific literature. According to one scientist, such material is in very short supply in Hanoi, but even this constitutes a "wealth much to envy" when compared with the south.

There have been reports of discrimination against scientists who worked for the south during the war. The latest information from Ho Chi Minh City however, suggests that northern scientists now in the south are making a major effort to bring their southern colleagues back into the fold. A major obstacle is the lack of available scientific equipment; the accommodation is there, but not the technical support, and it appears there is little the government can do to improve matters at present in the current economic conditions.

- The official British response to Vietnam is somewhat confusing. The Ministry of Overseas Development (ODM) and the Foreign and Commonwealth Office are known to be concerned with human rights in Vietnam, and new aid programmes are being refused until they are sure that no violations of rights are taking place. But in Vietnam itself, the British Ambassador has bought some £2,000 of much-needed scientific literature for biologists working at the Vietnam Scientific Research Centre in Hanoi He is apparently allocating a further £2,000 for books next year.

- Back in Britain, neither the Royal Society nor the British Council appears to be doing much to promote contacts with Vietnamese scientists, despite discussions earlier this year about inviting one or more Vietnamese scientists to the UK. A Royal Society official said it was "into China at the moment". But a leading British scientist has urged the Society not to abandon its interest in the scientists of Vietnam who are in urgent need of assistance. The Royal Society, he said, could do much to help, simply by making and maintaining contact with the Vietnamese.

Alastair Hay

India gets ready to tune in to its satellite

THE building of seven ground receiving stations has begun as the first stage in preparing for the Indian National Satellite (INSAT) programme. The stations will be linked next March with a fractional transponder aboard an INTELSAT satellite above the Indian Ocean.

The INSAT project, costing six crore, is planned to provide remote areas with communications. By the time INSAT-I is launched in 1981, 28 more earth stations will be built all over the country.

INSAT-I is a multipurpose domestic communications satellite with a seven year lifetime to be built by the US Ford Aerospace Corporation. It will provide nation-wide direct television broadcasting to community receivers in rural areas, and continuous meteorological data in the visible and infrared.

Of the 35 ground stations to be built, six will be mobile, four by road and two by air. The one at New Delhi will be the biggest, acting as the control and monitoring station for the others. For meteorological studies about 110 unmanned data collection platforms will be installed at inaccessible spots. INSAT-I will give a cloud picture over the Indian Ocean, the Arabian Sea and Bay of Bengal every half hour.

As well as the Department of Space, other agencies like Posts and Telegraphs, Indian Meteorogical Department and the Ministry of Information and Broadcasting will be responsible for the establishment and operation of the INSAT network Most of the equipment needed to build the first seven earth stations will be imported, but Indian-made equipment will be used for subsequent stations The total INSAT project will cost Rs 175 crore with a recurring expenditure of Rs 11 crores per annum. ☐

Third World seeks low frequency broadcasting

THE non-aligned countries should seek a suitable frequency for direct sound broadcasting via satellite from the World Administrative Radio Conference (WARC) when it meets next year. This was decided at a three day conference on "Satellite in Broadcasting" among the non-aligned countries recently held in New Delhi.

According to experts at the conference direct sound broadcasting via satellite would enable the member-countries to use relatively inexpensive and mobile receivers The Indian Information and Broadcasting Minister Shri L. K. Advani said that high costs and the need for high-level expertise need not deter the member-countries from using satellites for communications Costs could be reduced through collective efforts, he said, and the technical expertise was already available in the developing world.

The purpose of the conference was to prepare a comprehensive report on the technical, economic, legal and political aspects of satellite broadcasting which will be presented at the forthcoming meeting in Tanzania of the Committee for Cooperation among the Broadcasting Organisations of Non-aligned Countries.

The experts felt that the selection of a particular mode of TV or radio transmission must depend on local conditions. They outlined a way of choosing the best mode taking into account the geography and available infrastructure of the individual country. They also decided to work out a way of exchanging TV and radio programmes among the member countries currently using the INTELSAT system.

Directly linking the domestic satellist of non-aligned countries is not yet possible because they transmit at high frequencies. The conference therefore agreed to urge the WARC to allot a frequency lower than 54 GHz —the lowest frequency band so far used. India is likely to ask for a long wave frequency because of the work she has done on long wave frequency propagation technology for low cost and long range broadcasts.

Dilip M Salwi

US carcinogen control threatened by costs

THE US Department of Labour's Occupational Safety and Health Administration (OSHA) seems to be losing the fierce battle that it has put up against being required to carry out detailed cost-benefit analyses of attempts to regulate occupational exposure to toxic substances

OSHA director Dr Eula Bingham, previously professor of environmental health at the University of Cincinnati Medical School, remains adamant that such analysis is not required by the Occupational Safety and Health Act of 1969, beyond ensuring that no action threatens the overall survival of a particular industry.

OSHA is far from giving in to the attacks of those who claim that further regulation is merely aggravating the country's inflation problems. This week, for example, the Department of Labour was expected to announce a new standard for occupational exposure to lead of 50 micrograms per cubic metre of air—four times lower than existing permitted levels—despite its own studies showing that this will have a substantial economic impact on the lead-storage battery industry

However, two recent events indicate the increasing pressure on OSHA to act not just on scientific evidence—or lack of evidence as the case may be—to protect workers' health but also to consider the economic implications.

The first is a statement from the Regulatory Analysis and Review Group, an offspring of the Council on Wage and Price Stability widely distrusted by environmental and labour groups In its comment on OSHA's proposed scheme for classifying and regulating chemical carcinogens, the review group echoed opposition to the scheme by the US chemical industry, criticised its 'inflexilibity' and claimed that the cost of implementing it would be "potentially quite substantial, well in excess of $1 billion."

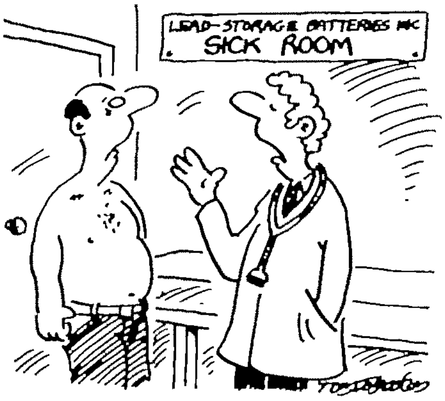
Similar pressures are also beginning to come through the courts. Last month, a federal appeals court in New Orleans set aside proposed new benzene exposure rules proposed by OSHA in June, on the grounds that the agency had failed to demonstrate a "reasonable relationship" between anticipated benefits and costs.

OSHA has already indicated that it will appeal against the court's ruling, a significant departure from earlier legal decisions which had accepted that such cost-benefit analysis was not necessary. But it accepts that if the ruling stands, then it would be required to shift its strategy; "if one has enough interpretations that this is demanded, then one would do it", Dr Bingham said.

The agency's reluctance to engage in such analysis seems based on three fears about how it might undermine OSHA's mandated efforts to protect the health of US workers. The first is that a requirement to carry out detailed cost-benefit studies would overburden an understaffed agency.

The second fear is that, as far as information on costs is concerned, OSHA would have to rely heavily on data provided by the industry itself, which it feels might be overstated

Thirdly there is a feeling that occupational health is an area in which scientific uncertainties are so high that any attempt to place definitive values on degrees of risk, etc., would merely disguise how such judgments reflect broader social values, and that these could be better dealt with if openly acknowledged.



"You're suffering from a bad case of Federal Appeals Court decisions, aggravated by inflation problems!"

"There is in scientific terms no evidence of a 'threshold'. But there is evidence that as you reduce the exposures, you are reducing the risk. If there are a few fibres or molecules left, theoretically someone somewhere might get cancer from it. At that point a social decision has to be made," according to Dr Irving J. Selikoff director of environmental sciences, Mount Sinai Hospital, New York

The problems caused by the scientific uncertainties were illustrated by the public controversy last month over a statement released by the National Cancer Institute, the National Institute of Environmental Health Sciences, and the National Institute for Occupational Safety and Health, claiming that up to 20% of all cancer deaths might be attributable to occupational exposure

Erroneously described by the US media as the results of a "new federal study", and frequently hardened to the claim that 20% of cancers were attributable to such exposure, the report was in fact a position paper put together rather hurriedly to meet OSHA's deadline for comments on its carcinogen proposals—and was given premature publicity when Labour Secretary Ray Marshall quoted extracts at a trade union conference.

The main message of the statement is that earlier estimates suggesting one to five per cent of cancers can be attributed to occupational exposure appear to be "unrealistically low"

However, the American Industrial Health Council, an industry-sponsored group which has been leading the attack on OSHA's carcinogen proposals, criticised the 20% figure as based on "unwarranted speculation".

Emphasising the council's support for the one to five per cent estimate, Dr Fred Hoerger, chairman of the AIHC's scientific committee, said that "the predicted massive increase in cancer due to occupational exposure in the study is not supported by current knowledge of cancer rates, worker exposures, or numbers of workers exposed".

The debate has demonstrated the gulf that exists between the scientifically conceivable (represented by the NCI position), and the scientifically demonstrable (on which AIHC argues regulation should be based).

It is a gulf which OSHA feels would be prematurely foreclosed by translating the debate into one of costs against benefits, given the problems of adequately defining either. Industry has been impressing on the president's economic advisers that, with rapidly rising production costs, this is the only reasonable basis for legislation.

OSHA has so far taken a firm stand against being required to adopt industry's perspective. And it has suffered virulent attacks, such as the American Conservative Union's "Stop OSHA" campaign, for doing so. But it is not yet prepared to throw in the towel

David Dickson

Correction

On page 108 of last week's issue a small error may have caused some confusion in interpreting the UK's proposed new guidelines for genetic manipulation. In the third column, item 4, the experiments referred to are those listed under the third item in the box on pages 106 and 107, that is those in Category I* "for which at present there is no substantial evidence of risk. The chief candidates of this kind are the experiments in which *E coli* genes are cloned in *E. coli* organisms".

0028-0836/78/0276—0204$01.00

news in brief

● **US Academy confirms saccharin as potential carcinogen:** THE US National Academy of Sciences has confirmed that the artificial sweetener saccharin can cause cancer in laboratory animals, and that it is probably a 'low potency' carcinogen in humans.

In a report prepared at the request of Congress, which last year imposed an 18-month moratorium on a proposed ban of saccharin by the Food and Drug Administration, an academy review panel says that "even low risks applied to a large number of exposed persons may lead to public health concerns".

The panel says that saccharin may also enhance the potency of other cancer-causing agents, and suggests that it may in fact be more dangerous as a 'promoter' of other carcinogens than as a carcinogen itself.

The panel also expresses concern at the increasing quantities of saccharin being consumed by young children, mostly in diet soft drinks. The length of time which cancer takes to develop could mean that such children have a magnified chance of developing cancer later in life, the panel says in its report.

● **Reprocessing plant still closed:** Employees at the Windscale reprocessing plant are still waiting for British Nuclear Fuels Ltd and the Nuclear Installations Inspectorate to decide when to re-start the reprocessing of nuclear waste. The plant was closed two weeks ago after a potentially explosive build-up of hydrogen in one of the silos where magnox cladding material is stored. In a reply to questions from the conservation group Friends of the Earth, the Department of Energy said workers were not in danger from the release of radioactivity from the silo, but reprocessing would not restart until an investigation revealed the cause of the build-up of hydrogen and if any measures needed to be taken to prevent a recurrence. A number of questions remain to be answered. For example, why, after 15 years of storing magnox in this manner, has the build-up of hydrogen not occurred before? A spokesman for British Nuclear Fuels told *Nature* that they wanted to be sure they understood what had happened before restarting reprocessing.

● **US judge claims low levels of PBBs "not toxic".** A county circuit court judge in Michigan has ruled that the low levels of polybrominated biphenyls (PBBs) to which cattle in the state were exposed after fire retardant had been mistakenly mixed with animal feed, were "not toxic". As a result, he dismissed a claim for damages issued by a Michigan farmer who slaughtered his herd on realising that they had eaten contaminated feed provided unknowingly by the Farm Bureau Services, a farmers' cooperative, in 1973. In a 177-page opinion handed down after the longest trial in state history, Judge William Peterson said that the animals had been slaughtered needlessly because of public fear aroused by "incompetent and dishonest" scientists, veterinarians and lawyers who, he claimed, were trying to capitalise on the disaster.

Fears about the potential carcinogenicity of PBB have been raised because all other halogenated aromatic hydrocarbons tested to date have turned out to be carcinogenic. Research on PBB is now being carried out at the National Cancer Institute in Bethesda, Maryland. However, referring to the arguments of those who had warned of the potential long-term hazards of low-level exposure to PBBs, Judge Peterson said: "Professionals have forsaken objectivity and their usual standards of inquiry to accept unquestioningly, as a basis for their expressed opinions, reported facts that were not factual."

● **$1.5 million to erect statue of Einstein:** The US National Academy of Sciences announced this week that it is to erect a statue of Albert Einstein, three times life-size in the academy's grounds on Washington's Constitution Avenue. The statue, which will be unveiled next spring in a ceremony honouring the centennial of Einstein's birth, will be carried out by Robert Burks, who sculpted a portrait head of the physicist in 1953. The cost of the statue, the base and the ground preparation will be more than $1.5 million. A fund-raising campaign is being organised by the academy among the US technical community.

Announcing the plans for the statue this week, Dr Philip Handler, president of the NAS, said: "It is our hope that this statue will serve several public purposes—as a tribute to the enormous analytical and creative powers of this unique scientist to whom we owe so much, as an evocation of his profound spirituality and his concern for mankind, as a reminder that Einstein found in this country refuge from tyranny, and finally as an appreciation of the accepted place of science in our civilisation."

Meanwhile, in Europe, two interdisciplinary scientific meetings in Munich and Ulm marked the beginning of an international series of meetings to be held throughout 1979 to commemorate Einstein's birth on March 18, 1879. At the meeting in Ulm, Paul Dirac, who worked with Einstein at Cambridge and Princetown and who was awarded the Nobel Prize for physics in 1933, paid a tribute to "the excellence of Einstein's theory of gravitation".

● **Indian shuffle:** The new Secretary in the Indian Department of Science and Technology is Professor M. G. K. Menon. He will also serve as director-general of the Council of Scientific and Industrial Research. These posts became vacant with the departure of Dr A. Ramachandran to head the UN Centre on Habitat in Nairobi. Professor Menon is at present chairman of the Electronics Commission and secretary to the Department of Electronics and was for several years scientific adviser to the Minister of Defence. Well-known in the international science policy world, he has served as a member of the UN Secretary-General's Advisory Committee on the Application of Science and Technology to Development. His research in the fields of cosmic rays and elementary particles was largely done at the Tata Institute of Fundamental Research, of which he was director from 1966 to 1975

● **Britain joins in China exchange:** China is continuing to expand its scientific cooperation with western countries. Up to 100 Chinese research workers are to come to UK scientific laboratories for periods of about four years, under the terms of an agreement between the Royal Society and Mr Hu Ke-shih, vice-president of the Chinese Academy of Sciences, which was signed on 10 November. Mr Hu was leader of a delegation of scientists and Academy administrators who have just concluded a three-week visit to the United Kingdom as guests of the Royal Society. The group visited many university departments and research establishments such as the Rutherford Laboratory at Chilton and the Imperial Cancer Research Fund Laboratories in London. The agreement comes soon after a similar deal to exchange post-graduate students between China and the United States.

Should scientists attend the ICUS?

● When the third International Conference on the Unity of Sciences (ICUS) was held in London in November 1974, scientists were made aware of the link between the International Cultural Foundation, the conference organisers, and Mr Sun Myung Moon, the head of the much criticised Unification Church (Nature 251, 661; 1974). Since then, scientists have been divided over whether to attend subsequent sessions of ICUS. Here, Professor N. Kurti of the Department of Engineering Science, Oxford University explains why he feels justified in attending them.

THE seventh International Conference on the Unity of Sciences (ICUS VII) will take place in Boston, Mass., 24–26 November, 1978. No other series of scientific conferences has engendered so much passion, largely because these conferences have been financed and run by the International Cultural Foundation, one of the 50-odd organisations founded and presided over by Mr Sun Myung Moon, the wealthy, and passionately anti-communist South-Korean industrialist and businessman.

Wealth, strong political bias, success in business are not normally considered unacceptable characteristics in sponsors of conferences, but Mr Moon has one further attribute which is at the bottom of the animosity which the activities of the Moon-organisation create: he is the founder and head of the Unification Church which has hundreds of thousands of followers in South Korea and Japan—though its active membership in Western Europe and North America is probably well below 15,000 He is regarded by his followers as the new Messiah called by God to finish the work begun by Jesus Christ—and to my knowledge has never made an explicit disclaimer.

The Unification Church has been strongly attacked for its forceful proselytising activities and accused of brainwashing young people and alienating them from their families. It has many aspects which I find distasteful. The following excerpts from an interview Mr Moon gave to American Newsweek International are revealing: "God has hand-picked me" (The basis of an intense personality-cult). "The line-up in Panmunjon is like the line-up between the heavenly world and the satanic world" (President Park's South Korea seems to me a strange sort of heaven). "If one of my disciples denounces his parents he is not really my disciple" (How many of the Moon-disciples who did break with their families were expelled from the Church?).

It is not surprising that the following two questions should have been asked often: can a conference sponsored by a militant and politically motivated organisation which many regard as a danger, not only to the spiritual well-being of young people, but to the structure of society as a whole, do its work in an unbiased, objective fashion without being influenced by the views and beliefs of its sponsors? Are the scientists, among them many world-famous figures, allowing themselves to be used as propaganda material for the Unification Church? Having attended five of the six conferences held so far I shall try to answer these questions.

The first conference, organised by Mr Edward Haskell, author of the book *FULL CIRCLE, The Moral Force of Unified Science,* and held in New York in November 1972 was a dismal affair This is not surprising, since the above book, which formed the basis of the meeting, contained such choice proposals as periodic tables for the "Plant Kingdom", the "Animal Kingdom", "Human Society", etc. After all if science is "unified" then what goes for chemistry goes for other disciplines!

Such was my disillusionment with this first ICUS that in the summer of 1973 I declined an invitation to attend the second conference in Japan. I did the same when I was asked a year later to attend ICUS III to be held at the Royal Lancaster Hotel in London. However when I noticed that several of my colleagues for whom I had great respect were associated with the conference and had helped to shape its programme, I accepted, and did not regret it. ICUS III, together with ICUS IV held in New York in 1975, were, in my view, the best of this series.

One might well ask whether anything worthwhile can come out of conferences devoted to the unity of sciences—science being used in the wider sense of the word, equivalent to the German *Wissenschaft* or the Russian *Nauk*. Those who search for or want to believe in a 'unity of sciences' are often tempted to transfer concepts appropriate to one discipline to a totally different one and proclaim the result as a proof of 'unity'. Mr Haskell's periodic tables for botany, zoology, sociology are examples, so are Mr Moon's speculations about the origins of energy given in his address to ICUS V: "Without there first being a subject and an object pair, it is impossible to produce energy. That is to say, the relationship of a subject and object is indispensable as in the case of an atom where the proton (which is the subject) and the electron (which is the object) must both be present before beginning to interact". Hence "Energy is the phenomenon resulting from the process of the two (subject and object pair) becoming one". The rest follows: happiness is the result of "mind and body being united in one". Illness is the result "of the subject and object elements of the body failing to attain unity and harmony"—the medicine prescribed by the doctor "restores the harmonious unity".

If 'unity of sciences' is an ill-chosen aim of this series of conferences, the choice of the titles of the individual conferences was equally poor. What can one make of 'science and absolute values' (ICUS III), 'the centrality of science and absolute values' (ICUS IV), 'the search for absolute values: harmony among the sciences' (ICUS V)? But fortunately conferences are not determined by titles and slogans but by the quality of the participants and their interests, and even meaningless clichés can lead to useful conclusions and the crystallisation of ideas.

The following examples may illustrate this point At ICUS III in London one of the four committees spent two days on lectures and discussions under the general heading 'the idea of the university in a troubled world' One of the papers had the daunting title 'international education: a search for cultural and conceptual isomorphisms', but fortunately it had as an explanatory motto a quotation from Mark Twain:

> "I went next to the Secretary of War . . . I said there was nothing so convincing to an Indian as a general massacre. If he could not approve of the massacre, I said the next surest thing for an Indian was soap and education Soap and education are not as sudden as a massacre, but they are more deadly in the long run; because a half-massacred Indian may recover, but if you educate him and wash him, it is bound to finish him some time or other. It undermines his constitution; it strikes at the foundation of his being."

There was a lively discussion by philosophers, historians, economists, physicists, etc., on the question of whether or to what extent one civilisation should impose its system of education on another. As one participant said: "Is the educational system developed in Europe during many centuries fruitful for the Bantu child in a surroundings of tribe-togetherness?" Another paper under the same general heading was entitled 'cognitive limitations and public decision making' and led to an examination of the relative roles of intuition and statistical analysis in decision making

As in ICUS III so in ICUS IV (New

York) the interaction between developed and developing countries came under scrutiny. Thus the Committee which discussed 'the university, research institutions and society' returned again and again to that particular question, as the following examples show:

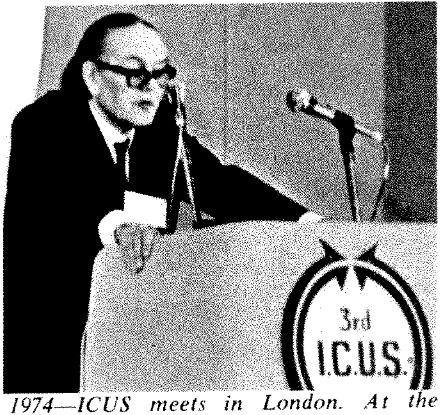
- Should universities in developing countries follow the principle enunciated in 1896, "only the best is good enough for Africa", or, should they eschew "excellence" in favour of "relevance" and be more attuned to local needs and aspirations?
- There seemed to be a need to scale down well-established technologies to suit developing countries, so that they are not forced to buy needlessly large plant, because nothing smaller was available.
- How can developing countries be persuaded to accept "intermediate technology" and not feel that they are being "fobbed off with the second best"?

I believe that even the severest critics of these conferences, agreed that the lectures and discussions were free of constraints, and that the proceedings of the conferences were not censored at all. The best proof can be found in Professor A. J. P. Martin's controversial lecture given at the closing session of ICUS III. One of his points was that there are too many people around, and that the population of the world, should be reduced by a factor 10. He proposed, for instance that the prison population should be reduced by submitting the inmates to carefully dosed X ray treatment which drastically shortens the expectation of life. These and similar suggestions, for example about selective breeding of humans, cloning etc., were delivered in deadly earnest, and I just could not judge how much of it was meant seriously and how much was *"pour epater les bourgeois"*, or rather *"les moonies"*. But what I find important is that Professor Martin's lecture, all of which was anathema to Unification Church tenets was printed in full in the proceedings.

It cannot be asserted that what was said at the unity of sciences conferences could generally be used in support of the Unification Church, but it is arguable that who said it could be of propaganda value. Indeed there have always been many Nobel-Laureates among the participants—at ICUS III in London 25 out of 140—and most ICUS Chairmen were Nobel Laureates: Lord Adrian (ICUS III), Professor R. S. Mulliken (ICUS IV), Sir John Eccles (ICUS V and VI), Professor E. P. Wigner (ICUS VII).

It is often said that the presence of so many Nobel Laureates and other well known scientists at the conference could be used to enhance the "respectability" of the Unification Church, and to neutralise the attacks made on it. Such fears are supported by the continuous tape-recording, filming and photographing at these conferences. But the remedy is often in the hands of the participants. When after ICUS VI the organisers were compiling a little glossy brochure about these conferences to lessen the effect of hostile press comments, participants who were to be quoted were asked for their agreement. I thanked the organisers for their courtesy, said that I regarded these conferences as *bona fide* scientific affairs which should be judged by the contents of the published conference reports and not by selected remarks of participants and others. My request not to be quoted was complied with.

To what extent are these conferences truly "international"? In 1975 I pointed out to the organisers that a conference to which people from the Communist countries are apparently not invited and which, while having quite a few participants from Israel, has none from Arab countries, could not be called "international". I made certain concrete suggestions and since then there is representation, albeit small, of both Arab and Communist countries.



1974—ICUS meets in London. At the microphone: Professor Archer Martin.

It is sometimes said that these conferences are used to make propaganda for the Unification Church and that the programme is arranged and the speakers chosen to suit the Church's book. My personal experience does not bear this out. As a member of the International Advisory Committee I frequently suggested speakers and participants whose religious and political ideas were far removed from those of the Unification Church, and yet my suggestions were invariably accepted. Of course many of the participants, among them scientists of considerable reputation, admire Mr Moon and the Church, but this does not interfere with their scientific judgment and in fact the Church, and for that matter Mr Moon, are hardly mentioned if at all.

I shall now answer the two questions I posed at the beginning of the article. The ICUS are *bona fide* scientific conferences free of political and religious bias. Not everyone may agree with the choice of topics, but this is not surprising for conferences which draw their participants from disciplines spanning most intellectual activities.

The second question, namely to what extent one's participation at ICUS furthers the aims of the Unification Church falls into three parts.

Has it any propaganda value? The films and recordings made at ICUS are, I believe, shown at Unification Church centres and functions, and it could be that the Church's aspirants and disciples are gullible enough to believe that the conference participants are *ipso facto* supporters of their Church and that the Nobel Laureates photographed with Mr Moon are his followers. Against this must be said that the conferences give ample opportunity for talking to the press, radio and to members of the Church, and many participants make it clear on such occasions that they have nothing to do with the Unification Church—perhaps even making critical remarks about it. For them ICUS is simply a multi-disciplinary scientific gathering.

Does acceptance of the fare and full board put one under an obligation to the International Cultural Foundation and to the Unification Church and colour one's attitude to them? If this were so, then scientists who regularly receive funds from many sources would be among the most diversely bribed members of the community owing allegiance to a multitude of organisations. Is the integrity of scientists really rated so low?

Can attendance at a conference sponsored by or connected with a religious or political organisation of whose activities one disapproves be morally justified? This is similar to the perennial question: should one attend conferences in countries with whose political system one disagrees, or which persecutes some of its citizens? There are those who say "No". For instance, there were some French people who even several years after the German occupation could not bring themselves to set foot on German soil.

But others say that adherence to such rigid principles, would make international scientific exchanges and collaboration impossible. One must follow one's conscience, and I personally have no moral qualms about attending an interesting and useful conference provided I am satisfied that in doing so I am not furthering aims or activities which are regarded as undesirable or even harmful. □

The fate of the Taj Mahal

SIR,—M. K. Agarwal has made a plea (2 November, page 10) that India should go ahead with the construction of the proposed oil refinery near the Taj Mahal and asks whether a poor nation can afford the luxury of keeping its monuments in their pristine beauty while it cannot provide a minimum for its people. While the intentions are laudable, I would like to contest the rationale.

If the shifting of the proposed site of the refinery by a few hundred miles is really going to affect the economic development of India to a significant degree, Mr Agarwal might indeed have a case. If there are scores of other marble monuments across the country which are all threatened by projects vital to reduce human misery, he may again be justified in criticising the efforts to save the Taj Mahal from corrosion, as one cannot go around cancelling all development schemes.

While changing the site of the refinery will only cause a bit of a headache for the planners and the bureaucrats, I cannot see much harm even in completely dropping the proposal. Looking through India's record since independence, no sincere observer can escape the fact that despite her impressive technological progress, the percentage of the population under the starvation line has remained around 60%. In absolute numbers, poverty has only increased.

The massive nuclear reactors, steel factories, refineries and the rest have benefited mostly the affluent and the urban middle-class. The majority of poor rural India, which should be the primary concern of any development project, has hardly gained from the industrial growth. In fact a case can be made that this western style technological progress has done more harm directly by increasing the stranglehold of the big industrialists, and indirectly by diverting valuable money from investment in the rural sector and in appropriate, labour-intensive, small scale technology. One could also argue that without fundamental social changes and agrarian reforms, any industrial progress in India can only be harmful.

Rather than being an economic liability, the Taj Mahal has always brought enormous foreign exchange to India. No tourist leaves the country without visiting Agra. Even commercially, it would be wiser to back the Taj Mahal rather than the refinery. Under these circumstances, the effort to save it from corrosion is hardly a luxury for a poor country.

If the construction of the oil installation goes ahead and the pollution does damage the monument irreparably, posterity will never condone this generation for sacrificing one of mankind's great architectural wonders for a very dubious (perhaps despicable) economic reason.

Discussing values and judgments

SIR,—I was most interested in your editorial comments of 20 July and feel constrained to address some of the inconsistencies they contain. In the first place, the separation of scientists from "the others" in terms of their ability to discuss values and human judgments and to deal with "convergent" rather than "divergent" problems seems to be both misleading and patently false.

During my years at university, I was constantly made aware of the barriers erected between the arts and sciences and was frequently told that "you are unable to understand these issues because your scientific training hasn't given you the necessary foundations for understanding general cultural and value systems." Rubbish! What I *have* observed during my years in university and subsequently is that non-scientifically trained graduates tend, if anything, to be a bit more dogmatic in their beliefs than scientists and are often unable to carry on philosophical discussions in a logical and consistent manner.

My education prepared me to make value judgments and the scientific method has fitted me admirably to address open-ended problems in a reasonable way.

All of your analysis seems to address reaction to recent evaluations of the Windscale inquiry and, specifically, the remarks of Professor David Pearce. You make further reference to the fact that the nuclear industry appears unwilling to discuss values—including the fear of nuclear weapons proliferation. Having chosen to "leave" such speculation (with which term you correctly indentified your ramblings), I should like to judge on its own merit your recommendation that school children be politically educated by requiring study projects linked with technological issues, such as the need for fast breeder reactors. In this way, you suggest, the humanist and the scientist (again, this false separation of the two aspects of each of us) can learn from one another. Assuming that you are referring to pre-university education, I very much doubt that your desired goals will be reached, since it is unlikely that such students are well enough prepared for the kind of in-depth study required to achieve these ends.

I should like to make further comment concerning the remarks of David Pearce in the following discussion of the values which are at the root of the nuclear debate. His statement proposing that opposition to nuclear power derives from differences in value systems strikes at the heart of this controversy; however, as I read them, his comments suggest that the "image of infinite credibility" is a cloak worn only by the nuclear industry and that they, so deceiving themselves, stand in the way of clear discussion of the values which lie beneath the issues discussed at Windscale. In a way this is rather humorous for, from my position on the other side of the controversy from that taken by David Pearce, it appears that this cloak is being worn by opponents of nuclear power development. I was glad to see him admit that there were many "men of reason" characterising the pro-nuclear stance but the impression given in his article was that this was the exception rather than the rule. With this same proviso, I could change the term 'industry' into the term 'environmentalist' and make the entire article read very much to my liking—perhaps proving, as Pearce suggests, that the debate has fallen to a very low level indeed.

A clue to the problem (which is raised by discussions such as the one presented by Pearce) is revealed when one considers the 'problem' of defining public accountability for decisions made in a social context. Institutions must be modified to accommodate other points of view, states Pearce, with the thinly-veiled threat that failure to do so will result in conflict (presumably including physical violence). I suggest that the real problem in the nuclear debate is the fact that institutions have been modified to the point where everyone, no matter where his expertise lies, presumes himself fully-qualified to speak on every issue and, for this reason, totally irrational points of view are given prominence simply because of their sensational value in the public eye.

Heaven help our society if orderly inquiry into questions such as that recently carried out at Windscale is replaced by mob rule because people such as David Pearce are unprepared to accept defeat when their values are weighed in duly-constituted public inquiry and rejected. Justice Parkers' report seemed a well-reasoned and impartial survey of the many questions brought up at the inquiry and the fact that he dismissed out of hand a number of alternative value systems proposed by some of the intervenors is not a result of his failure to understand but simply a judgment based on his understanding of the will of the people of Great Britain as expressed through past legal decisions and acts passed by their elected representatives in Parliament.

Food production has kept up

SIR,—I was disappointed to see in your pages (26 October, page 698) the myth that there has lately been an "inexorable increase in the world's population without a commensurate increase in food supplies". FAO data show that during the past two decades of rapid population growth, while population has grown at 2% per annum food production has grown by an average 2.8% per annum. These results have been discussed in detail in *World Futures* (C. Freeman and M. Jahoda (eds), Martin Robertson, London; 1978).

Powder metallurgy: new techniques, new applications

from Robert W. Cahn

CERAMIC objects—crockery, fine porcelain, furnace tubes, insulators—are made by starting from a powder, binding it (with water or adhesive), sometimes pressing the mass and then firing. The bulk of the powder never melts (though part of it may); by a series of physical processes including bulk and interface diffusion, the particles weld together, or sinter, and the pores between them close up. There is really no alternative, because most ceramics are too refractory to melt and, being brittle, the power particles cannot be squeezed together.

The idea of adapting sintering methods to metals seemed eccentric when it was first tried in Austria early this century, and the German term 'Metallkeramik' showed the origin of powder metallurgy as a variant of ceramic procedures. From the beginning, the attraction of powder metallurgy has been economy : a fairly complex shape can be made quickly and cheaply, without the problem of solute segregation inseparable from all forms of casting. In some special instances, powder metallurgy can create a product that cannot be matched by traditional means : the manufacture of long-lasting incandescent lamp filaments is the prime instance. (The progressive improvement of electric lamps, largely a matter of metallurgical ingenuity, is a fascinating chapter in the history of metallurgy). Apart from such special cases, powder metallurgy has generally been restricted to unsophisticated products, subject to modest demands.

All this is in the throes of change, and powder-metallurgical methods are beginning to be applied to demanding functions such as gas turbine disks and highly stressed airframe components. The reason is to be found largely in two very recent technical developments —rapid solidification processing and hot isostatic pressing.

Rapid solidification processing (RSP) is an American industrial development stemming directly from the techniques of splat-quenching of alloy ribbons from the melt (see *Nature* **252**, 100; 1974). An alloy melt is atomised and sprayed through a helium atmosphere and the fine droplets, usually in the range 25–100 μm diameter, are frozen very rapidly; the exact cooling rate is subject to many experimental variables, but an average rate of $10^6\,^{\circ}\mathrm{C\,s^{-1}}$ is quite accessible. The particles are then pressed and sintered and may subsequently be extruded or wrought in other ways. This technique of making final products has the advantages that macrosegregation is entirely eliminated, large amounts of solute can be held in metastable equilibrium which makes possible new levels of precipitation-hardening, and the consolidated product can have very fine grain sizes which in turn leads to great ductility at ambient temperature—even to superplastic behaviour.

The method is being applied to superalloys for jet engine parts, titanium alloys for airframe components and to aluminium alloys. It has been difficult to discover much about these developments, many of them shrouded in industrial secrecy—but publication has now begun. Much information about both powder quenching and consolidation is to be found in the proceedings of a conference on Rapid Solidification Processing.* The other up-to-date source is a review article by N. J. Grant, presented at the Third International Conference on Rapidly Quenched Metals, Sussex University, in July 1978; this will be published in the *Proceedings* by the Metals Society, London, in December 1978.

Hot isostatic pressing (HIP) is a new technique, pioneered in Sweden, with even wider potential. A chamber (which may be a fair part of a cubic metre) is subjected to high temperature—it can be well above 1,000 °C—and high uniform (isostatic) pressure—typically 1 kbar—transmitted by argon. The maintenance of such temperatures and pressures in such large volumes represents a technological achievement of a high order, with correspondingly high demands on safety precautions : in the early days of HIP an operator was suffocated in a sea of escaped argon.

Specimens for HIP consist of loose powder contained in a sealed evacuated can of metal foil or in a shaped die of glass or steel, and the process converts them in one operation into pore-free solids. Ordinary sintering of metals, without pressure, will not reduce porosity below 3–4%, and removal of that small porosity leads to a large improvement in strength, ductility, toughness and fatigue resistance at room temperature. A related function of HIP is its use for 'rejuvenation' of turbine blades. Creep of a cast blade in service generates porosity at grain boundaries, which limits creep life; HIP can entirely remove this porosity and thus effectively confer on the blade a new lease of life. This method is just beginning to be used in practice. A further development, in America, is the 'near-net shape' process. A shaped thick die of glass or steel is used to contain the powder : at high temperature and pressure, the die behaves as a quasi-Newtonian fluid and transmits hydrostatic pressure. Complex airframe components can be made from powder —which may have been made by RSP—directly as 100% dense shapes which require only a minimum of machining.

The combination of RSP and HIPping (the neologistic verb is firmly entrenched in America) offers, for the first time in many years, some prospect of enhancing the service temperature of turbine blades. This is because the problem of macrosegregation in castings has strictly limited the permissible alloy content of superalloys; RSP has removed this limitation and a new range of alloy compositions is now accessible. The main problem is that the fine grain size produced by RSP, desirable for applications at ambient temperature, is quite unacceptable for turbine blades—which must have very coarse grains. There are indications

that it may be possible to achieve such grains by recrystallisation after RSP followed by HIP, without loss of the precipitation-hardened microstructure that confers hot strength. In this connection, current theoretical work aimed at identifying the plastic processes that enable pore closure during HIP-ping may prove important, because the feasibility of recrystallisation is closely linked to the amount and nature of plastic deformation previously undergone by the metal. Activity in this field is very intense.

Yet another potentially very valuable use for HIP has just been proposed by U. Engel and H. Hübner of Erlangen, Germany (*J. Mater. Sci.* **13**, 2003; 1978). They HIP-ped, at 1 kbar and 1,260–1,360 °C, samples of cemented carbide (tungsten carbide particles cemented by films of metallic cobalt, made by conventional sintering combined with partial melting). These very brittle materials are used as tips for lathe tools subject to exceptionally severe demands. It was found that, after HIP-ping, all residual pores were completely eliminated, being filled by cobalt, which is itself not brittle. It appears that under HIP conditions the cobalt binder can flow freely between the carbide grains. Sophisticated methods of fracture testing were employed to examine the effect of HIP-ping on the resistance to brittle fracture, and it was found by statistical (Weibull) analysis that the mean fracture strength could be doubled, with a concomitant reduction in scatter of strength values. A critical comparison of observed flaw sizes with those computed from measured fracture strengths proved that the specimens were behaving as ideal brittle, flaw-limited solids both before and after HIP-ping. This very careful study indicates that HIP of cemented carbides should greatly increase the performance and life of lathe tools; moreover this should make economic sense as a production treatment, since cemented carbides are materials of high specific value. □

Megagauss magnetic fields in laser-produced plasmas

from M. H. Key

A recent paper by Raven, Willi and Rumsby (*Phys. Rev. Lett.* **14**, 554; 1978) describes the observation of an intense (1.8 MG) toroidal magnetic field surrounding the 30 μm focal spot of a pulsed (100 ps) laser focused on to a solid surface in vacuum. While it is intuitively obvious that $>10^{16}$ watt cm^{-2} laser intensity will create a hot plasma in the focal region, it is much less obvious that a toroidal magnetic field will be generated with a growth rate of 10^{16} G s^{-1}. Indeed it was not until 1971 that Stamper *et al.* (*Phys. Rev. Lett.* **26**, 1012; 1971) of the US Naval Research Laboratory (NRL) detected kilogauss magnetic fields with magnetic pick up coils 1 ~ cm from a laser-produced plasma, and gave a basic explanation of the field generation mechanism. Before this it had often been assumed that a desirable feature of laser-produced plasmas was the absence of magnetic field effects!

The pick up coils used by Stamper *et al.* measured the field only in the tenuous plasma resulting from free expansion into vacuum about $\sim 10^{-7}$ s after its creation and it was not possible to deduce the much larger field strengths occurring in the microscopic laser-produced plasma itself. The question was nevertheless of great interest because it seemed that the field strengths might be great enough to considerably modify the plasma behaviour with important implications for the developing ideas of laser fusion.

It was the NRL workers, Stamper and Ripin (*Phys. Rev. Lett.* **34**, 138; 1975), who tackled this problem by looking for, and observing in 1975, the rotation in the plasma of the plane of polarisation of a probe pulse of laser light by the magnetic field induced Faraday effect. Their results, indicating megagauss fields, were of a preliminary nature and subsequent efforts to reproduce them both at NRL and elsewhere were negative.

There developed a situation in which theoretical models of increasing sophistication such as that of Colombant and Windsor (*Phys. Rev. Lett.* **38**, 697; 1977) predicted the megagauss fields but only the doubtful NRL experiment had shown any direct evidence for the fields, and in particular very careful 4th harmonic optical probing experiments by Attwood at the US Lawrence Livermore Laboratory had shown no fields above 100 kG to be present when ~ 50 μm spherical glass shell targets were irradiated.

The paradox was resolved in 1978 when the NRL group devised a novel way to avoid a persistent problem of the optical probing experiments. 2nd or 4th harmonic generation using a fraction of the main laser pulse had hitherto been used as a convenient source of a synchronised optical probe pulse but the measurements were complicated by the emission of those same harmonics from the plasma itself. The solution found was to generate the 0.53 micron second harmonic but to further shift its wavelength by stimulated Raman scattering in ethanol to 0.6329 micron. This eliminated interference from plasma generated harmonics and in May 1978 Stamper *et al.* were able to report irrefutable confirmation of their earlier experiment showing megagauss fields (*Phys. Rev. Lett.* **40**, 1177; 1978) but there remained an apparent conflict with the absence of such fields in the microballoon target experiments of Attwood.

It was perhaps an illustration of the coming of age of the new SRC Central Laser Facility in England that Raven, Willi and Rumsby, having an experiment scheduled just a few weeks later than that at NRL were able to take advantage of the Raman shifting idea and further to improve the experiment by the addition of simultaneous interferometry. The latter enabled direct determination of the electron density distribution which must be known to unfold the magnetic field from the Faraday rotation angle θ since $\theta \propto \int_l B.n_e dl$. They produced an elegant set of results which gave the most accurate field determinations to date. Moreover their results removed the remaining discrepancy by confirming Attwood's low field values on 50 μm spherical targets and Stamper *et al.*'s megagauss fields on plane targets.

The current state of the art may be summarised by saying that the megagauss toroidal fields and associated tens of kiloampere currents do occur. The primary source of the field is known and in simple terms involves an imbalance in the diffusive flow of electrons in the plasma creating a current loop (Figure 1). The axial increase of electron number density N_e leads to an axial outflow of electrons and the radial decrease of T_e leads to a radial fall-off in this outflow. Charge conservation requires a current loop as illustrated and this thermoelectric type of generator creates a field increasing with time with

$$\frac{dB}{dt} \propto \nabla T_e \wedge \nabla n_e$$

and having a toroidal geometry as seen experimentally. The magnitude of the field is such that it has a significant pressure relative to the plasma (45% in the data of Raven *et al.*) and has a strong effect on electron diffusion by creating an electron cyclotron orbit diameter considerably smaller than the field free 90° deflection mean free path (7% in the data of Raven *et al.*).

In conclusion it is of interest to consider areas requiring further study. The relative importance of several other processes producing the magnetic field in addition to $\nabla T_e \wedge \nabla n_e$ is not yet fully clear. The effect of the field on heat flow

is also uncertain, first at the theoretical level as discussed by Max *et al.* (*Phys. Fluids* **21,** 128; 1978) and second because no experimental data have been obtained on the field strengths in the region of a plasma of above critical density where heat transport by electrons is the dominant process. ☐

Calcium control of enzyme reactions

from Michael J. Geisow

THE diverse roles attributed to calcium ion as a mediator of biological control have proliferated to such an extent, that the symbolic representation of this element at the focus of schematic cells has become a common sight in reviews. Many intracellular calcium-binding structures, membrane complexes as well as discrete proteins, have been reported. Which of these can be considered as sites of calcium-mediated control? The normal ionised calcium level in the cytosol of cells is low (0.1 to 0.01 μM). Even under conditions of 'activation' like the response to a hormone, calcium ion concentration probably does not rise much above 10 μM. Moreover, this increased concentration is not uniform because of diffusional barriers in the cytosol, and it is transient because of the action of membrane calcium pumps.

Subcellular structures which are potential targets of calcium dependent regulation, must consequently have dissociation constants for calcium of the order of 1 μM. Additionally, since intracellular magnesium concentration is relatively constant at 1 mM, calcium binding sites must have a selectivity of at least 10^3 for calcium over magnesium. As far as is known, only proteins can meet these calcium-binding requirements.

The most universally accepted protein effector of calcium-mediated control is troponin C (TnC), which makes muscle actomyosin ATPase sensitive to free calcium above about 1 μM (see *News and Views* **275,** 177; 1978). TnC has four divalent cation binding sites, of which two can only bind calcium. The protein molecule responds to bound cations with a large conformational change. TnC could be called the archetypal calcium receptor protein, since once actomyosin was recognised in non-muscle cells, the presence of proteins analogous in function to TnC was also anticipated. Kuo and Coffee (*J. biol. Chem.* **251,** 1603; 1976) isolated just such a protein from adrenal glands. Physically and chemically similar to TnC, this molecule bound two calcium ions with an apparent dissociation constant of 20 μM. This resulted in a considerable conformational transition, analogous to that undergone by TnC. Although it seems probable that this protein could activate actomyosin, the actual process regulated by the adrenal TnC remains undetermined.

By contrast, a variety of functions have been attributed to another intracellular calcium-binding protein, first identified in brain. This molecule, known as the calcium-dependent regulator or modulator protein (MP) has been purified from a wide variety of tissues. Although MP has chemical and structural homology with TnC, it is quite distinct and is two orders of magnitude less effective in stimulating actomyosin ATPase. At 1 mM Mg^{2+}, calcium ions bind to MP with an apparent dissociation constant of 3 μM (Wolff *et al.* in *Calcium Binding Proteins and Calcium Function*, 97, North-Holland New York; 1977). The modulator protein activates cyclic nucleotide phosphodiesterase, adenylate cyclase and red blood cell Ca^{2+}-dependent ATPase (Parett & Penniston *J. biol. Chem.* **253,** 4676; 1978). Both MP and TnC inhibit and reverse microtubule assembly in the presence of 10 μM Ca^{2+} (Marcum *et al. Proc. natn. Acad. Sci. U.S.A.* **75,** 3771; 1978). Indeed MP was localised by immunofluorescent labelling in the microtubule-rich mitotic spindle apparatus, implying its participation in the control of mitosis.

Many workers have found that the phosphorylation of membrane proteins is calcium sensitive. For example, Kruger *et al.* (*J. biol. Chem.* **252,** 2764; 1977) demonstrated that depolarisation of intact nerve-endings stimulated specific membrane protein phosphorylation, provided that this stimulus was delivered in a calcium-containing medium. Similar covalent phosphate incorporation occurred during histamine release from most cells (Sieghart *et al. Nature* **275,** 329; 1978). Recently Schulman and Greengard (*Nature* **271,** 478; 1978) showed that the phosphorylation of isolated nerve-ending membrane occurred in response to calcium and soluble cytoplasmic 'factors'. Purified MP was able to substitute effectively for the cytoplasmic proteins in the phosphorylation reaction. A common feature of the apparently diverse functions of MP is its connection with phosphate ester breakdown or synthesis. The essential link between all of the observations may have been provided by the identification of MP as a subunit of two protein kinases. Cohen *et al.* (*FEBS Lett.* **92,** 287; 1978) and Barylko *et al.* (*FEBS Lett.* **90,** 301; 1978) report that MP is a subunit of muscle phosphorylase kinase and myosin light chain kinase respectively. These kinases are sensitive to 1 μM Ca^{2+}, and it is likely that regulation occurs through the interaction of the intrinsic MP with a regulatory subunit of the kinases.

The modulation of cyclic nucleotide phosphodiesterase, adenylate cyclase and membrane Ca^{2+}-stimulated ATPases also seems to occur as the result of reversible binding of a calcium-MP complex to a regulatory subunit of these enzymes. It is interesting to speculate whether the regulation of microtubule polymerisation might result from an interaction of MP with tubulin GTPases (see David-Pfeuty *et al. Nature* **272,** 282; 1978.)

Although the status of TnC and MP as calcium-dependent regulators is now established, the way in which non-muscle cells could become activated as

Michael J. Geisow is a member of staff at the National Institute for Medical Research, London.

0028–0836/78/0276—0211$01.00

a result of contraction or phosphorylation/dephosphorylation processes remains obscure. In secretory tissues the universal response to raised cytosolic calcium is the release of secretory products stored in subcellular vesicles by fusion of vesicle and plasma membrane. Creutz *et al.* (*J. biol. Chem.* **253,** 2858; 1978) report the isolation of a 47,000 molecular weight protein which promotes the close association of adrenalin-containing granules isolated from adrenal glands. Contacts resembling the apposition of secretory granule membrane with plasma membrane before fusion, form reversibly in the presence of calcium ions above about 10 μM. It was not established whether the granule-aggregating protein itself bound calcium, or became bound as a result of a calcium binding event on the granule itself. The latter alternative is more consistent with the observations of Gratzl *et al.* (*Biophys. biochim. Acta.* **470,** 45; 1977). These authors claim that aggregation and fusion of isolated secretory granules from several tissues occurs in the presence of 10 μM calcium. Magnesium ions could not substitute for calcium in this process. A protein, rather than a lipid calcium-binding component, is implicated, since liposomes made from the lipids found in secretory granules do not aggregate or fuse at such low calcium concentrations.

The ability of the TnC-like proteins to confer calcium sensitivity upon enzymic processes, perhaps by combining with a common regulatory protein subunit, potentially accounts for the multiple intracellular effects of calcium. However, it is still premature to claim the uniqueness of these proteins as calcium receptors in non-muscle cells, and the characterisation of other recently identified members of this class of calcium-binding proteins is eagerly awaited. ☐

The enigma of poxviruses

from Arie Zuckerman and Charles Rondle

THE global eradication of smallpox is probably the greatest public health achievement of the 20th century. Eradication was possible because of the availability of a highly effective vaccine prepared from vaccinia virus. Yet one of the most controversial aspects of vaccination is the origin of vaccinia virus, and in particular whether it is derived from smallpox or cowpox. It has also been suggested that vaccinia might have arisen as a hybrid between these viruses. It appears, however, that vaccinia virus is most closely related to cowpox. Phylogenetically, the whole group probably derives from one common ancestor and its differentiation must be connected with the domestication of animals by the first agricultural settlers of the human race.

The second reason for the success of the smallpox eradication programme is that smallpox is a human disease with no known animal reservoir or insect vector. But nevertheless, problems remain since natural poxvirus infection of nonhuman primates does occur (see **241,** 425; 1973).

Monkeypox virus was first identified in 1958 during an outbreak of a vesicular skin disease in captive *Cynomolgus* monkeys in Copenhagen (von Magnus *et al.*, *Acta Path. microbiol. scand.* **46,** 156; 1959). The distribution of the rash was similar to that of smallpox in man and the virus was recognised as a poxvirus by its structural features under the electron microscope and by its serological relationship to vaccinia virus. By 1969, monkeypox virus had been isolated from captive nonhuman primates, or from their organs, on 10 occasions, including one isolation from an anteater which temporarily shared a cage with an infected orang-utang. Between 1970 and the middle of 1978, human cases of monkeypox were reported from West and Central Africa with five (15%) deaths, a mortality rate similar to smallpox in that region. Furthermore, most cases clinically resembled smallpox. The prospect of the spread of monkeypox from man to man was alarming, but in the event possible secondary transmission only occurred in two cases—of 55 susceptible family contacts only 2 (3.6%) acquired the infection, and there have been only 33 recognised cases among over 200 million people in a period of more than 8 years. But the natural host and vector of monkeypox virus remain unknown, despite the fact that there are reports of 'smallpox' in monkeys as long ago as 1767 (Arita & Henderson *Bull. Wld Hlth Org.* **39,** 277; 1968).

Whitepox virus is a more worrying puzzle. This virus was first identified in a Dutch laboratory in September 1964 during routine processing of Asian *Cynomolgus* kidney tissues (Gispen & Brand-Saathof, *Bull. Wld Hlth Org.* **46,** 585; 1972) and could not be distinguished at the time from smallpox virus by laboratory tests. The name 'whitepox' was given to the isolates because in contrast to monkeypox they produced small dense white pocks on the chorioallantoic membrane of the developing chick embryo. Between 1971 and 1973, this virus was isolated on four occasions from primate kidney tissues derived from a chimpanzee and a sala monkey, and from two rodents, *Mastomys natalensis* and a squirrel-like rodent captured in Zaire (Marennikova *et al. Bull. Wld Hlth Org.* **46,** 61; 1972; *Acta Virol.* **20,** 80; 1976). Experimentally, a whitepox virus inoculated into *Ceropithecus aethiops* monkey caused a generalised rash and illness. Whitepox virus still cannot be distinguished from smallpox virus by laboratory tests (Fenner *Prog. med. Virol.* **23,** 1; 1977), and it therefore remains both a puzzle and a threat. The fact that no infections with smallpox-like virus have occurred in Zaire during the 7 years since the last smallpox case was identified is at least reassuring. It does seem, therefore, that animal poxviruses are not a threat to the global eradication of smallpox, but the need for constant surveillance and laboratory studies continues.

Marennikova and Shelukhina (see this issue of *Nature,* page 291) now report that whitepox viruses isolated

NATURE

A hundred years ago

THE *Daily News* Quebec correspondent telegraphs as follows:—"After long study and many experiments Prof. Bell has made an important discovery in connection with the telephone. It is well known that the telephone has been a comparative failure in England on account of the fatal induction generated by the contiguity of other wires. Prof. Bell has discovered simple and efficacious means whereby not only is induction prevented, but the clearness and force of the telephonic vocalisation greatly increased. Prof. Bell tells me that practical demonstration of the importance of the discovery will be given in London as soon as the necessary preliminaries are complete." We give this statement as published in the *Daily News,* though it must be received with some caution.

From *Nature* **19,** 14 November, 46; 1878.

0028–0836/78/0276—0212$01.00

from apparently healthy monkeys and rodents are stable clones which are present in populations of monkeypox virus. Inoculation of hamsters with monkeypox virus resulted in asymptomatic infection but virus was isolated from the hamsters for up to 7 weeks after inoculation. Four out of the 35 isolates showed that these were stable viruses identical with natural whitepox and which could not be differentiated from smallpox. It seems likely that the white clones were present in the original inoculum and were preferentially selected. This selection occurs in an unpredictable manner. Since whitepox viruses cannot be distinguished from smallpox virus, the results may be interpreted as an indication of the possible origin of smallpox viruses from monkeypox. □

What is climatology?

from T. M. L. Wigley and P. Brimblecombe

JUST what is the meaning of climatology as a discipline, and what qualifications or interests does one have to have in order to contribute to climatology? The recent conference 'Evolution of Planetary Atmospheres and Climatology of the Earth' in Nice* emphasised, perhaps more strongly than any similar gathering, the range of fields which now contribute to our understanding of past climates. Very few of the participants could call themselves climatologists in the traditional sense of the word; they came variously from astronomy, geology, space physics, geochemistry, statistics, glaciology, oceanography, botany/palynology and other areas of science.

The conference itself had very ambitious aims There were papers dealing with climatic change on all time-scales, from about 10^9 years down to seasonal changes, beginning with a review of the longest time-scale changes on Earth, Mars and Venus by T. Owen (State University of New York, Stony Brook). He pointed out some of the problems with the assumption that the Earth originally had a highly reducing atmosphere (NH_3, CH_4), and stated the present general view that CO_2 and H_2O were important original constituents. This hypothesis was strongly supported by A. Henderson-Sellers (University of Liverpool) and A. J Meadows (University of Leicester) who gave results from a model which, on the basis of a CO_2–H_2O atmosphere, was able to explain the so-called 'faint Sun paradox': that is, the apparently anomalous lack of extensive ice cover on the Earth during its early history when the solar output was substantially less than today. A number of other papers dealt with this contentious issue, an issue that has ramifications for the origin of life on Earth. Most experimental synthesis of the prebiotic formation of organic molecules begin with a strongly reducing atmosphere, but this and other recent work suggest that such a beginning is not a prerequisite for the evolution of life.

Bridging these and shorter time-scale studies was the study of mid-Cretaceous global climate presented by P. Larsson (University of Lancaster) which suggested that dinosaurs may well have been warm-blooded animals. On the 10^6 to 10^7-year time-scale, N. J. Shackleton (University of Cambridge) presented stimulating evidence on Tertiary climatic change which is at least as challenging to the theoretician as the faint Sun paradox. In the mid-Tertiary, for a period of $\sim 10^7$ years, it seems that tropical and subtropical climates were some 4 to 6 °C cooler than today: that is, colder than during any of the 17 or so glacial cycles which have occurred in the past 2.5×10^6 years. For the climatologist, such a climate picture is, at present, very hard to understand. It lies outside the possible realm of Milankovitch effects which are now generally accepted as being fundamental to the more recent glacial cycles. The Milankovitch theory was, however, treated with healthy scepticism in W. Broecker's review paper (Columbia University). The paper by A. Berger (Louvain University, Belgium) indicated that monthly insolation data may be more important in determining the climate-orbit link than the data used by Broecker, but Broecker's suggestion that there may still be important internal mechanisms was reinforced by some interesting modelling experiments reported by M. Ghil (New York University) and K. Bhattacharya (Columbia University). Their work, though based on very simple models, produced purely internal cyclic variations with nearly square-wave behaviour. They impose an imaginative albedo-temperature relation to obtain this cyclic solution. The amplitude of the cycles is reasonably in accord with past evidence, a particularly interesting factor since the modelling experiments based on external forcing (*à la* Milankovitch) invariably fail to obtain a climate signal with realistic amplitude These models were represented by G. R. North (University of Missouri) and J. A. Coakley's (National Center for Atmospheric Research, Boulder) elegantly simple seasonal model, and by the models discussed by E. Bernard (Institut Royal Météorologique, Brussels) and by C. Nicolis (Institute d'Aéronomie Spatiale, Brussels) (although the latter's efforts were directed towards longer time-scale climatic fluctuations), and, in a later session by the work of M. Hantel (Bonn University).

The Milankovitch theory was once again strongly supported in the paper by J D. Hays and D. W. Cooke (Lamont-Doherty Geological Observatory, Columbia University). They showed that major climatic fluctuations were approximately in phase between Northern and Southern hemispheres over the past 5×10^5 yr, and that the well-established periods of 23,000, 41,000 and 100,000 yr also show up in Antarctic deep-sea cores. These authors also suggested that the glacial to interglacial transition, as evidenced by a reduction (by a factor of ~10) in Antarctic summer sea ice, might have occurred in as little as a few hundred years, and that such changes preceded major ice volume changes in the Northern hemisphere.

Interesting papers on 3×10^5 and 3×10^4-yr time-scales were presented by J. C. Duplessy (Centre des Faibles Radioactivites, Gif-sur-Yvette) and C. Lorius (Laboratoire de Glaciologie, Grenoble), but the latter part of the conference was devoted to a much shorter time-scale. A brief review by T. M. L. Wigley (University of East Anglia) pointed out that the European Medieval warm epoch (approximately AD 1000–1200) was probably not a global phenomenon, in contrast to the apparent ubiquity of the climax of the Little Ice Age (AD 1500–1700). This picture provided a backdrop to a number of detailed descriptions of climatic events during the past 1000 years, descriptions which were highlighted by the interesting dendroclimatological studies of F. H. Schweingruber, O. U. Bracker and E. Schar (Swiss Federal Institute of Forestry Research, Birmensdorf), A. Berger and co-workers (Louvain University), and F. Serre (Marseille University). Schweingruber's group are pioneers in using wood density as a proxy climate indicator (closely related to summer temperature), and these workers showed some intriguing evidence of teleconnections between North America and Europe on the 5-year time-scale.

One of the most immediately significant contributions came from C. E. Leith (National Center for Atmospheric Research, Boulder, Colorado) on the mechanisms of short period climatic fluctuations He gave a most lucid explanation of predictability, based largely on the work of Madden If, as

T. M. L. Wigley and P. Brimblecombe are in the Climatic Research Unit at the University of East Anglia.

is so in the present state of the 'art', weather is essentially unpredictable beyond about a 5-day period, then the statistics of observed climate variability imply, necessarily, that month to month climate changes are, for many parts of the world, largely unpredictable. Although this is an undisputable statement of present capability, there are some rays of hope sneaking over the horizon For instance, there is some indication that, if we knew more about the mechanisms of 'blocking', then there would be greatly improved predictability in these situations. Furthermore, as S. H. Schneider (Boulder, Colorado) pointed out, we may still be able to develop good selective prediction schemes (for extreme events, for example) even without improving day to day forecasting skills or our understanding of the meteorology of blocking.

Schneider himself presented one of the most interesting review papers, on the effects of man's activities on climate. Although man's effects, on the regional and global scale, are not yet distinguishable from 'natural' climatic fluctuations, the potential for more significant effects is high. Because of the immobility of society *en masse* we are, in most places, unable to adapt rapidly to changes in the climate of marginal regions (be these changes natural or man-made), so possible man-induced changes are of considerable concern. In particular, the magnitude of CO_2 effects before the middle of next century could be 1 or 2 °C overall at the surface, and much greater in polar regions. This would have serious consequences. This point was reinforced in an engrossing summary given by Professor H. Flohn (Bonn University). He considers two factors of prime future importance. First, in the past there is strong evidence of extremely rapid climatic change—as fast as, for example, a 5 °C drop in summer temperature in less than 100 years. Should this happen in the future, there could be dramatic consequences. Second, the production of CO_2 by fossil fuel burning is liable to be a major problem within 100 years. On a reassuring note, however, Flohn pointed out that even a large warming would probably not, as some people have suggested, cause a rapid melting of the Arctic sea ice. Partly because of feedback effects and partly due to the large time constant for the Greenland Ice Sheet the minimum time for such melting would be at least 1000 years And, although this is certainly not a cause for complacency, we are still not absolutely certain that increased CO_2 will lead to warming. All models used to date to examine this question have failed to handle possible cloudiness changes in a realistic way: we just do not know how to do so at present. Still, the various models, many of which parameterise clouds very differently, all predict warming, so the odds are strongly in favour of such an outcome and it is a possibility which must be taken with utmost seriousness.

Although many significant advances have been made in climatology in recent years, it is sobering to consider these in the light of the first climate model; that of the Egyptian scribe who said, around 3000 BC, "the Sun warms the Earth". ☐

Histone genes displayed

from P. J. Ford

HISTONE proteins are of central importance to the molecular biology of higher organisms since with DNA they are involved in chromatin structure and function. The five types of histone, H1, H2A, H2B, H3 and H4 are found combined with an equal amount by weight of DNA in nuclei of eukaryote cells. The relative amount of each histone type appears to be regulated since they are present in equal molar amounts, except H1 at half molar amount. In addition there are in many organisms developmental stage and tissue-specific sequence variants within each of the major histone groups. Quite how these variants relate to chromatin structure and function is not clear, but they provide a useful handle for studies on the control of specific gene expression during development and differentiation. As is often the case recent advances in understanding histone gene structure stem from the discovery of a particularly favourable system, early sea urchin development, in which rapid cell division demands considerable rates of histone synthesis to accommodate the high rates of DNA synthesis, and from which histone mRNA is readily extracted (Kedes & Gross *Nature* **223**, 135; 1969). Estimates of histone gene numbers in sea urchins suggested the presence of several hundred to a thousand copies of each histone gene depending on species (Kedes & Birnstiel *Nature new Biol.* **230**, 165; 1971). In this respect sea urchins may be an extreme case since other phylogenetically diverse groups have considerably fewer (20-100) copies of each histone gene.

Isolation by molecular cloning techniques of DNA segments coding for sea urchin histone genes has led to proof that genes for all five histone types occur together in one repeating unit in the order H4, H2B, H3, H2A and H1 and that each structural gene is separated from the next within the unit by spacer DNA. Recently (Schaffner *et al. Cell* **14**, 655; 1978) Birnstiel and his colleagues have presented DNA sequences for more than half the total histone gene repeat unit known as h22 from the sea urchin *Psammechinus miliaris*. These include complete sequences for the H3 and H2A genes plus almost complete sequences for the other three structural genes and entirely confirms earlier maps of this particular DNA fragment. From a comparison of known histone protein sequences with the amino acid sequences which would be generated by translation of these particular structural genes it seems likely that unit h22 is active in early development and does not code for the specific histone subtypes found in sea urchin sperm. Additional information derived from these sequences is that h22 histone coding sequences do not contain inserted untranslated sequences like those seen in mouse and rabbit globin and chicken ovalbumin genes. Histones are not synthesised as longer precursors and there is no evidence for substantial regions which might be translated in any other reading frame to give other types of polypeptide.

As well as sequences for structural genes Schaffner *et al.* have determined sequences for regions at the beginning and end, called prelude and trailing sequences, respectively, of the structural genes and for some of the spacer regions. As they state: "If it were true that identical functioning of the regulatory signals require exactly identical primary structures, then sequence comparisons between preludes and trailing sequences around different histone genes should reveal some sequence homologies Our sequence comparison by computer analysing runs of three or more nucleotides has been relatively unsuccessful in that it has disclosed no long runs of sequences held in common between different spacers or preludes, with the possible exception of a short sequence in two spacer regions and a sequence of twenty nucleotides in the prelude regions of the H2A and H4 structural genes". I suppose we are to conclude that either the sequences presented do not cover regulatory sites or that they function in a way which does not require extensive sequence identity.

Sequences and maps of restriction enzyme sites in spacer DNA of h22 has revealed that unlike the spacers found in *Xenopus* ribosomal and 5S RNA genes there are no small repetitious sequences present Consequently no spacer length variation like that in the

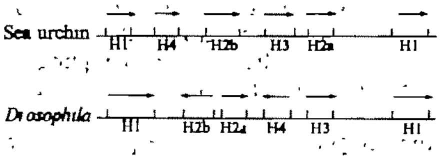
Xenopus rRNA genes due to the presence of different numbers of small repeating units is observed in sea urchin histone DNA. This is not to say that length variation does not occur, since Overton and Weinberg (*Cell* **14**, 247; 1978) studying independently isolated histone gene units from another sea urchin *Strongylocentrotus purpuratus* report that there is both length and sequence variation between different histone gene units. They have been able to show that this variation is found more extensively in histone DNA isolated from a group of sea urchins. More remarkable is that histone DNA variants from individual sea urchins are limited to a few of the major classes seen in the population as a whole. Each of five individuals were distinguishable on the basis of histone gene length and restriction site variants. Before attempting to assess what this means it will be necessary to follow histone gene patterns in offspring of individuals of known histone genotype.

During early sea urchin development two sets of histone genes are active. Kunkel and Weinberg (*Cell* **14**, 313; 1978) provide evidence that a full length histone DNA repeat, called pCO1, from *S. purpuratus* will hybridise to histone RNA from both cleavage and blastula stages. The hybrids formed with blastula transcripts are more easily melted (10 °C) and more easily digested with ribonuclease suggesting more extensive base mismatching than hybrids with cleavage stage transcripts and hence blastula transcripts probably derive from another type of histone gene. They suggest that pCO1 is preferentially transcribed during cleavage and not during blastula when transcription of other histone genes predominates. Such changes in transcription are also reflected by changes in histone protein synthesis (Newrock *et al. Cell* **14**, 327; 1978). Changes in the *in vivo* patterns of histone synthesis during early sea urchin development may be transferred to an *in vitro* protein synthesising system along with mRNA isolated from the appropriate developmental stages. There is no evidence from these studies for control of histone subtype synthesis at the translational level, since new subtype synthesis *in vivo* is closely coupled to appearance of mRNAs which can be translated *in vitro* to give products with very similar properties to the new histone subtypes seen *in vivo*.

Recently (Lifton *et al. Cold Spring Harbor Symp. quant. Biol.* **42**, 1047; 1977) the structure of *Drosophila melanogaster* histone genes has been reported. There are some interesting differences as well as similarities in comparison with sea urchin genes. Both contain all five histone coding sequences together in a single repeating unit, but the order and the direction of transcription differs. As the promoters for transcription have not been identified yet it is not clear whether each structural gene has its own promoter or whether there is a single promoter for each repeat unit, the resulting polycistronic primary transcripts being processed to give separate mRNAs. In *Drosophila* the fact that transcription must proceed in both directions makes a single promoter for both strands very unlikely. Lifton *et al.* have made an unsuccessful search for high molecular weight RNA molecules which hybridise to histone DNA and that might be considered polycistronic transcripts. They consider it most likely that *Drosophila* histone genes are transcribed independently, possibly from two divergent promoters and a single promoter. In sea urchins it is still unclear where transcription is initiated. The fact that clustering of different histone structural genes together in one unit is a very old and evolutionarily stable organisation suggests that it might be important perhaps in allowing the coordinated transcription of equal numbers of genes, thus ensuring correct histone protein stoichiometry, providing all histone messages are translated equally efficiently. □



A threat from fluorocarbons?

from a Correspondent

Do chlorofluorocarbons (CFCs) represent a threat to the ozone layer, with possible implications for life on this planet? This question, prompted by the hypothesis of Molina and Rowland (*Nature* **245**, 810; 1974), was addressed at 'Fluostrat '78'*. According to Molina and Rowland the breakdown in the stratosphere of CFCs, whose industrial production mushroomed in the early 1970s, would produce Cl and ClO which would reduce ozone through a catalytic cycle.

The representatives of the chemical industry went to great pains to point out the very large amount of work on this problem which has been sponsored by the Manufacturing Chemists Association. They pointed to the range of qualities which has made the CFCs such ideal propellants The search for alternatives has, so far, produced no compounds with even comparable properties. However, the case to be answered remains whether or not CFCs could reduce the amount of ozone in the atmosphere, thus allowing increased penetration of potentially harmful ultraviolet radiation.

The scientific proceedings of the symposium suggest that we are still some way from a definite answer to this question. Indeed, the interesting feature to emerge was the increasing awareness of the uncertainties in all the areas of research and of the great complexity of the system which atmospheric scientists are attempting to study.

A particularly important area of research is the investigation of the levels of CFCs present in the troposphere, in an attempt to determine their lifetimes there. J. E. Lovelock dealt with the difficulties in calibrating the electron capture gas chromatographs used in the measurement of CFCs. In a very elegant process, he has used an exponential dilution chamber to dilute accurately weighed amounts of CFCs to the parts per trillion (10^{-12}) level and then tested the calibration assumptions made by most experimenters. These assumptions have been found by Lovelock to be invalid over the range of mixing ratios measured in the atmosphere. Indeed, an intercomparison of a prepared standard sample of CF_2Cl_2 by 12 different laboratories showed very large differences between their findings.

It is apparent that the natural cycle of chlorine compounds in the atmosphere is not well understood. There was, in particular, much energetic debate regarding the apparently high levels of stratospheric ClO which have been reported by Anderson *et al.* (*Report to Congress and to the Administration of the Environmental Protection Agency on the National Aeronautics and Space Administration, 1978*).

B. A. Thrush of Cambridge University, in reviewing atmospheric chemistry, dealt with the importance of the coupling between the cycles of the nitrogen and chlorine compounds The theme of the importance of meteorological coupling mechanisms was taken further by R. J. Murgatroyd (Meteorological Office, Bracknell) and J. A. Pyle (Oxford University). The numerical models which have been used in predictive studies have generally been rather simple, one-dimensional (height only) representations of the atmosphere The need for models which represent meteorological processes rather better is apparent and these

0028-0836/78/0276—0215$01.00

models should include the important coupling between chemistry, radiation and dynamics. Model calculations of ozone depletion were shown to be sensitive to these feedback mechanisms.

The problem of just what effect an increase in ultraviolet radiation might have on the population was discussed by R. H. Mole of the Medical Research Council Radiobiology Unit, Harwell. He found faults with a wholly uncritical acceptance of the correlation between latitude and occurrence of skin cancer Changing social conventions in dress and increasing mobility of the population are certainly likely to be very important factors

In summary, the symposium in reviewing recent work highlighted many uncertainties There is clearly a need for a better understanding of the chlorine budget, the continuing measurement programme being very important. Further improvements in numerical models are necessary, with greater emphasis on the meteorology of the problem Finally, it would be of great help to the planners who must make some decision on the use of CFCs if a more reliable understanding of the possible medical effects of an increase in ultraviolet radiation dosages were gained. □

Microscopic optical potentials

from P. E. Hodgson

An international workshop on microscopic nuclear optical potentials was held at the University of Hamburg from 25 to 27 September.* Organised by Professor H V. von Geramb, it attracted over 100 participants and provided a welcome opportunity to review the recent progress in calculating optical potentials from the nucleon-nucleon interaction. Powerful methods of calculating the optical potential for finite nuclei have been developed by Jeukenne, Lejeune and Mahaux in Liège and by Rook and Brieva in Oxford (*Nature* **253**, 163; 1975 and **269**, 750; 1977). The resulting potentials fit the data quite well, without further parameter adjustment. This opens the way to a detailed understanding of the interaction of nucleons and groups of nucleons with nuclei, assists the phenomenological analyses of experimental data, and should stimulate further accurate experimental work The latest developments in these calculations were reviewed by C. Mahaux and by F A. Brieva, and related work by I. McCarthy (Adelaide) and M Weigel (Munich).

At lower energies, the structure of the target nucleus affects the interaction, and the effects of the coupling to the single-particle and collective states may be included in the calculation of the imaginary part of the potential by explicit summation over intermediate states. Work of this type was described by V. A Madsen (Oregon), N. Vinh Mau (Orsay) and Van Giai (Orsay), and applied to nucleon and alpha-particle scattering from ^{40}Ca and ^{208}Pb

It is now clear that the Saxon-Woods form factor universally used in optical model calculations is not always a sufficiently accurate representation of the potential. Improvements can be made by using microscopic form factors, or by supplementing the potential by an extra term depending on the orbital angular momentum L, or by altering the shape of the potential in a systematic way to fit the experimental data. A microscopic basis for an improved potential was provided by Y. C. Tang (Minnesota) who used the resonating group formalism to show that antisymmetrising the wavefunctions in a folding model calculation gives rise to parity-dependent terms in the potential. These take account of exchange processes and become less important as the mass difference between the interacting particles increases.

In some interactions there is a significant difference between the optical model predictions and the experimental data, and there is an obvious physical reason. It is then possible either to incorporate the physical effect in the calculations, or to add an extra phenomenological term to the potential. An example of this is the strong coupling to low-lying collective states which in the case of sub-Coulomb scattering of heavy ions causes the cross section to depart from the usual Fresnel form. This was discussed by A J. Baltz (Brookhaven), who showed that the data can be fitted by the addition of a long-range dynamic absorption potential that can be obtained in closed form Further analysis of this process was presented by G. Baur (Jülich). Another example is provided by the strong coupling to particular reaction channels This alters the elastic cross section in a way that can be fitted by an L-dependent potential, as shown by Mackintosh (Daresbury) He also showed the value of model-independent analyses of elastic scattering

Extensive work on the unification of the bound state and scattering potentials was presented by M M. Giannini (Genova), and other global phenomenological analyses by A. Tarrats (Saclay) and by H. Leeb (Vienna). A new method of measuring cross section ratios was described by S. M Austin (Michigan) and extensive measurements of proton scattering by light nuclei by M Pignanelli (Milano).

The analysis of the scattering of composite particles by nuclei has not yet been developed to the same stage of sophistication as nucleon scattering. Several folding models give semi-phenomenological potentials that often fit the data quite well, but much of the important physics, especially the effects of antisymmetrisation and exchange, is still hidden in the adjustable normalisation parameter A pioneer study of deuteron interactions was presented by A. A. Ionnides (Surrey) but apart from this the development of microscopic potentials for composite particles is still in the future. Meanwhile, a wealth of accurate data on the elastic scattering of deuterons and alpha-particles was presented by several groups, and in most cases they are very well fitted by optical model analyses

Calculations of the imaginary part of the optical potential for heavy ions were reviewed by D M. Brink (Oxford) who also described a new approach using the Feynmann path integral method. This can be used to relate the imaginary potential to the friction coefficient in heavy-ion scattering. D. F. Jackson (Surrey) showed how the extreme sensitivity of the alpha-decay rate to the potential barrier can be used to define the optical potential more precisely. A repulsive-core alpha-particle potential that gives the energies and widths of unbound cluster states and also fits the elastic scattering was described by K. A. Gridnev (Leningrad) Molecular states in heavy ion potentials were reviewed by W Scheid (Giessen).

A fully microscopic description of heavy-ion reactions is not yet practicable, but considerable progress has been made using the time-dependent Hartree-Fock method P G. Reinhard (Mainz) has used this method to determine the collective Hamiltonian and hence the quantum corrections to the optical potential

The meeting showed the extent and vitality of studies of all aspects of optical model potentials. The techniques for calculating microscopic potentials have now been established for nucleons, and much work remains to be done to improve the calculation of small terms and to apply the method to a wide range of nuclei and energies. At the same time it will be extended to composite particles, to link up with the very extensive phenomenological analyses that have already been made.

P. E. Hodgson is in the Department of Nuclear Physics at the University of Oxford.

review article

Advanced batteries

B. C. Tofield
Materials Physics Division, AERE Harwell

R. M. Dell
Materials Development Division, AERE Harwell, Oxfordshire, UK

J. Jensen
Department of Chemistry, Odense University, 5230 Odense, Denmark

Advanced-battery technology has been the basis of an Anglo-Danish interdisciplinary scientific project. The technological and economic aspects of advanced battery installations in vehicular and stationary applications are discussed in this article.

ADVANCED batteries provide a particularly good example of interdisciplinary science and technology. To gain the scientific understanding necessary to predict appropriate materials for constructing such devices and then technically to build a successful device, one must bring together such subjects as structural chemistry, solid- and liquid-state electrochemistry, interfacial and surface science, ceramics, corrosion science and metallurgy. Solid state physics and computer modelling of ionic motions within phases and across interfaces also have an important part to play. To assess the economic viability of particular systems one has to take account of projected battery performance parameters as well as such features as cost and availability of raw materials, processing technology, construction and fabrication costs, installation costs, safety, pollution and a comparison of these aspects weighed against alternative means of doing the same job.

An advanced battery project has recently started at several laboratories in the UK and Denmark. Seven institutions, four in England and three in Denmark, are collaborating to do research on materials for advanced batteries, together with technological and economic assessments of advanced battery installations in vehicular and stationary applications. The work is partially sponsored by the Commission of the European Communities.

β Alumina and the sodium–sulphur battery

Advanced batteries have stimulated much interesting work in solid-state chemistry and electrochemistry in recent years[1–3]. The seminal discovery was the observation of very high sodium ion mobility above room temperature in sodium β alumina by Weber and Kummer (at Ford) just over 10 yr ago[4]. β alumina, one of a family of closely related compounds, has a layer structure as shown in Fig. 1. Four layers of close-packed oxygen atoms contain four fold and six fold coordinated aluminium in an atomic arrangement analogous to that found in spinel, $MgAl_2O_4$. The formula of β alumina, however, $Na_{1+x}Al_{11}O_{17+\frac{x}{2}}$ is not compatible with an infinitely extending spinel structure. The relative lack of aluminium is reflected in the fact that every fifth layer of oxygen atoms is only one-quarter filled. The sodium ions are found in this relatively empty layer[5].

β Alumina was so named because it was thought to be an isomorph of aluminium oxide, and the crystal structure was essentially solved before the war[6]. However, the unusual electrical properties of sodium β alumina were not discovered until recently. When the electrical conductivity at 300 °C was measured, and it was realised that the current carriers were exclusively sodium ions and not electrons, the application of materials like β alumina to a modern generation of power batteries was quickly realised. In the sodium–sulphur battery, patented by Ford, instead of solid electrodes separated by a liquid electrolyte, as in the conventional lead–acid car battery, for example, sodium β alumina is used as a solid electrolyte, specifically conducting sodium ions, between liquid electrodes of sodium metal and sulphur (Fig. 2). The cell voltage, 2.08 V, is derived from the chemical reaction between sodium and sulphur to produce sodium polysulphide and the theoretical energy density, about 750 Wh kg^{-1}, is high compared with that of the lead–acid battery, only about 170 Wh kg^{-1}. Such impressive energy densities immediately indicated attractive possibilities for electric vehicle propulsion and other applications.

0028–0836/78/0276—0217$01 00

The novelty of the properties discovered in sodium β alumina may be estimated from the fact that, although its melting point is around 2,000 °C, several A cm^{-2} of current may be passed across the electrolyte at 300 °C. The key to the rapid sodium ion mobility lies in the crystal structure and the low potential energy path for sodium migration this produces. β Alumina thus provides a happy hunting ground for molecular dynamics and potential energy calculations[7,8] as well as for experimental assessment of the effect of chemical structure variations and ion exchange on the electrical behaviour[9,10]. Many other cations including the other alkali metals and ammonium, protons and hydronium ions can be ion-exchanged for sodium by immersion in suitable molten salts or by other techniques[11].

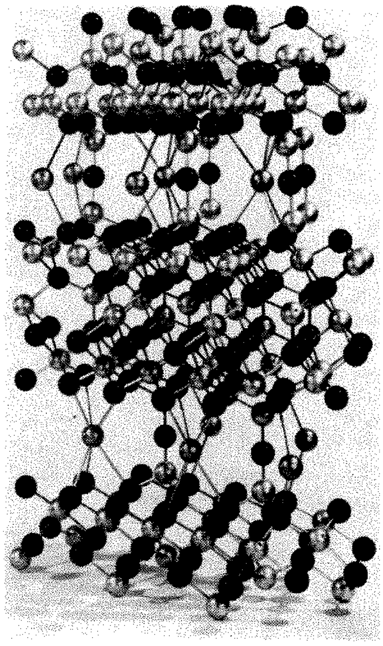

Fig. 1 The β alumina structure. The densely populated close-packed 'spinel blocks' containing aluminium and oxygen ions separate the mirror planes which contain the mobile sodium ions. The density of oxygen atoms in the mirror planes is only one-quarter of that in the spinel blocks. The separation between mirror planes is just over 11 Å.

Although the gross features of the β alumina structure have been known for a long time, the detailed crystallography of the mirror plane, vital to an understanding of the electrical properties, is still only partially understood. Recent work using neutron diffraction at Brookhaven National Laboratory has shown[12] that the occupation of the mirror plane is considerably more complicated than originally thought. Sodium β alumina as normally produced is invariably non-stoichiometric with x in the formula usually between 0.2 and 0.3, and it is now generally accepted that this non-stoichiometry is accommodated by extra oxygen as well as extra sodium occupying positions in the conducting plane. The actual conduction mechanism of sodium is, therefore, complex and has not yet been fully unravelled. Indeed, the mirror plane chemistry of the β alumina structure can almost be called a branch of science in its own right.

One interesting new development at Harwell has been the characterisation of hydrogen-conducting β aluminas. These have been studied electrochemically and gravimetrically[13,14] and by neutron diffraction[15]. A proton-conducting ceramic could have interesting applications, for example, as a medium temperature fuel-cell electrolyte.

An added complication in β alumina chemistry is that several variants of β alumina exist[9] and so-called β″ alumina, which has cubic rather than hexagonal stacking of the spinel blocks (as in β alumina) has a higher conductivity than β alumina but is more susceptible to attack by moisture and is not so rugged. A compromise between conductivity and strength may be obtained by having both β and β″ present in electrolyte tubes. High resolution electron microscopy has shown[16] that the mixing can occur on the unit cell level as well as by a mixing of macroscopic grains. The intergrowth of β- and β″-alumina layers is shown in Fig. 3. The higher conductivity of β″ alumina is related to the fact that the different stacking of the spinel blocks produces two equivalent cation sites in the mirror plane rather than one favoured site and one relatively blocking site as in β alumina, and also to the absence of interstitial oxygen in the mirror plane[12]. β″ alumina is non-stoichiometric with regard to sodium, an essential feature for rapid ionic motion, but this is compensated by magnesium substitution, $Na_{1+x}Al_{11-x}Mg_xO_{17}$ (with x usually between 0.2 and 1.0) or by lithium substitution rather than by interstitial oxygen.

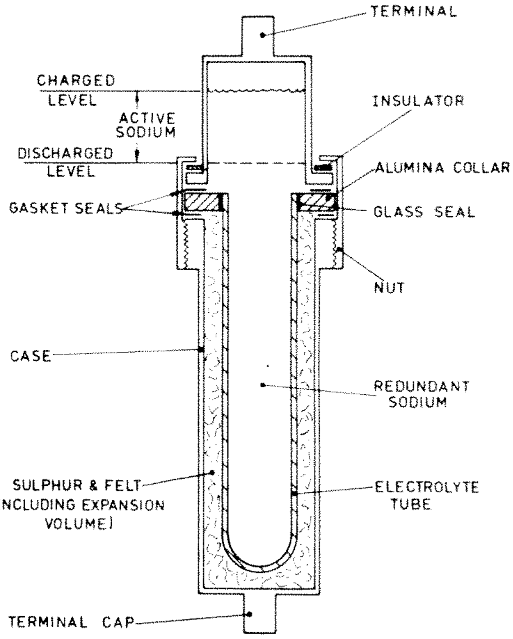

Fig. 2 A schematic model of the sodium–sulphur battery which uses a sodium β alumina solid electrolyte as the separator between liquid electrodes (sodium anode and sulphur cathode). The operating temperature is 300–400 °C.

The new science of rapid ion transport

The discovery of β alumina and the promise of the sodium–sulphur battery have had parallel effects in science and technology. Many programmes in several countries were set in motion to develop sodium–sulphur batteries[17]. Nevertheless, although development has been going on for 10 yr, batteries are not expected to be commercially available until the mid 1980s.

At the same time as the work on battery development, many scientific centres, particularly in the US and Europe, started programmes to try to discover new fast ion conducting solids, both for sodium, other alkali ions, and anions such as fluoride. For several years this search was not very successful, but as the structural requirements have become better understood alternative materials have begun to emerge (see, for example, refs

18–20). However, no sodium or other alkali ion-conducting materials have yet been found which show significantly improved electrical properties over β alumina and none has as low an activation energy for ionic mobility (0.13 eV) (ref. 21). Fast ion-conducting materials have been listed and discussed[22,23], and the field of solid state ionics and the technical applications, including advanced batteries, has recently been surveyed[30].

One new and important concept which has emerged, involving fast ion conductivity, is the insertion compound or solid-solution electrode[24]. In a solid-solution electrode there is both rapid ion transport and electronic conductivity. But a third vital ingredient is the presence of a range of stoichiometry involving the mobile ion. Fast-ion conducting materials of this type, therefore, can be used, not as electrolytes as is the case for β alumina, but as battery electrodes with either a liquid electrolyte or a solid electrolyte. In the latter case one is using fast ion-conducting materials to make an all-solid-state battery. In the former case, although the arrangement of solid and liquid phases is formally similar to that found in conventional lead–acid or alkaline batteries, the power-to-weight ratios obtainable using modern materials are much higher than was previously thought possible.

In contrast to solid electrolytes, where sodium is generally found to be the most mobile of the alkali ions, most good solid-solution electrode materials so far discovered act best as conductors of lithium ions, although this distinction may not survive further research. One of the most attractive solid-solution electrodes so far reported[25] is based on titanium disulphide, TiS_2. This is a layer material with adjacent layers of sulphur atoms held together only by van der Waals bonding (Fig. 4). TiS_2 and other similar chalcogenides of the transition metals can absorb alkaline cations between the sulphur layers. There is a slight expansion of the crystal axis perpendicular to the layers but otherwise no change in the crystal structure. For lithium going into titanium disulphide there is a continuous region of non-stoichiometry from TiS_2 to $LiTiS_2$. Moreover, the partial free energy of intercalation is relatively constant across the whole range. Titanium disulphide is quite light, cheap and readily available and the lithium–titanium sulphide battery developed by Exxon[26], which has an organic electrolyte and works at room temperature, has a theoretical energy density of 480 Wh kg^{-1}. This is already quite close to that of the sodium–sulphur couple, and there is the advantage of room-temperature operation, the absence of liquid alkaline metals, and, possibly, considerably reduced problems in fabrication and corrosion.

Solid-solution electrodes therefore provide a field of complementary scientific interest to solid electrolytes and have at least equal potential application in battery systems. Apart from the presence of rapid ion transport, the extra keys to the utility of solid-solution electrodes lie in the interfacial aspects of ions being able to pass directly between the electrolyte phase and the electrode without any change in crystal structure of the electrode or the necessity to form a new compound by electrocrystallisation (compare the electrode reactions in lead–acid and alkaline batteries), and the ability of the electrode to absorb a sufficient quantity of the active ion to provide systems with very attractive energy densities. The use of metal chalcogenides as reversible electrodes has recently been reviewed[27].

A third, more traditional, concept being applied in advanced battery design is the application of fused-salt electrolytes. The use of fused salts, of course, implies elevated temperatures, but fused salt electrolytes can allow the drawing of higher current densities than is presently possible with solid electrolyte-based batteries. The most notable current development using a fused-salt electrolyte is the lithium–iron sulphide battery, developed at the Argonne National Laboratory[28]. This battery operates at around 400 °C and uses a fused salt eutectic electrolyte mixture of lithium chloride and potassium chloride. Using a lithium–aluminium anode, the theoretical energy density is 650 Wh kg^{-1}, similar to that of sodium–sulphur, and the expected actual energy densities of the two systems are comparable.

The need for advanced batteries

Battery development is, therefore, at an interesting stage of transition and, although estimates differ and there will obviously be wide variations from country to country, considerable applications for advanced batteries can be foreseen in the medium- and long-term future. Future electrical energy supply will almost certainly have an increasing contribution both from nuclear power and from alternative sources such as wind, waves and solar energy. Irrespective of the relative importance of these various sources, there will be an increasing need for energy storage capacity to match the demand to the supply characteristics. Although desirable, a radically improved standard of energy economy does not change such a need. There are several ways of achieving such matching but electrical storage by secondary batteries offers one attractive method over a short timescale.

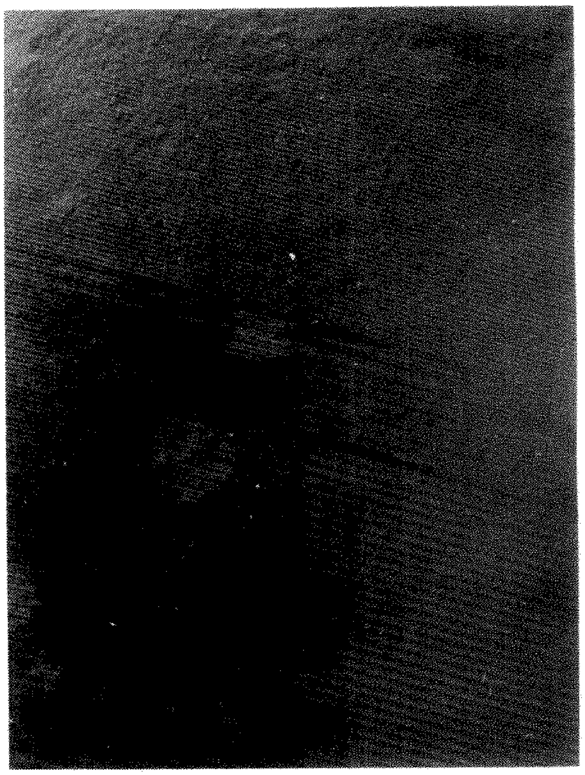

Fig. 3 A lattice image of a mixture of β alumina and β'' alumina showing intergrowth of the two structures at the unit cell level. The electron beam is parallel to the mirror plane. Although the spinel block thickness is the same in both materials, the space groups are different. Double diffraction is allowed in the $P6_3/mmc$ space group of β alumina and the 'forbidden' (001) reflections can be imaged in suitable conditions to generate 22 Å fringes. Only the space-group-allowed 11 Å spacing reflections are seen for β'' alumina.

Additionally, efficient off-peak energy utilisation by relatively non-polluting electric vehicles will surely play an increasingly important role in the total picture[29], although for such a role to be significant it is particularly important that electric vehicle technology is developed to provide products which are economically competitive with internal-combustion-engine-powered vehicles. The extent to which this can be achieved depends critically on the development of cheap, long-lifetime, high-energy batteries capable of many hundreds of cycles at deep discharge and high current density to provide the range and performance capabilities which will be demanded.

Advanced secondary batteries will therefore fulfil three roles in the field of efficient energy utilisation, or energy conservation in the medium- to long-term future: (1) load levelling in the electrical generating system; (2) smoothing of supply to demand for alternative energy sources; (3) electric vehicle traction; not only will this reduce dependence on oil supplies but will also improve urban air quality. Additional applications, of large industrial importance, such as nautical or aviation power systems, will, inevitably, also be found.

The second generation of advanced batteries

Rechargeable battery manufacture is still dominated by the lead–acid battery, but because of its low energy-to-weight ratio this system does not offer a very attractive solution to the roles just outlined. Industrial development of traditional alkaline electrolyte batteries (for example, nickel–zinc and nickel–iron) should produce improved power systems for vehicular traction in the relatively near future; thus the realisable energy density of a nickel–zinc battery is expected to be about 90 Wh kg^{-1}, over twice that of the lead–acid battery.

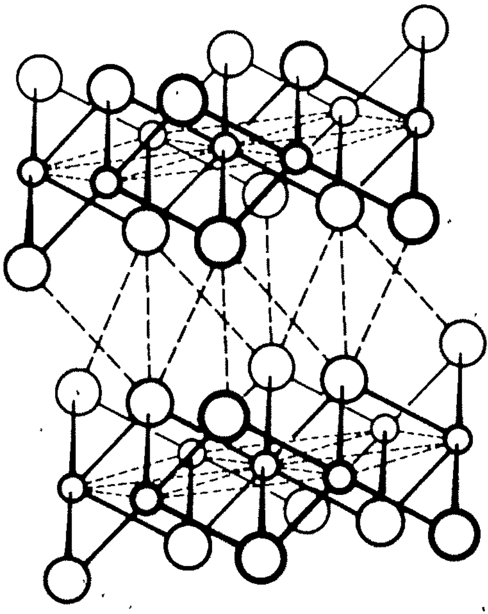

Fig. 4 The cadmium iodide structure adopted by titanium disulphide, TiS_2. The structure is layer-like with STiS sheets held together only by van der Waals interaction between the sulphur layers. The metal (titanium) atoms are in octahedral coordination by the anions (sulphur).

The present (first) generation of advanced batteries have considerably superior theoretical energy densities to the traditional types, but the weight penalty of engineering safe and reliable sodium–sulphur and lithium–sulphur batteries seems to be considerable, so that the realisable energy density may be no more than 150 Wh kg^{-1} for both these systems and perhaps may be as low as 110–120 Wh kg^{-1}. The improvement over the anticipated development of the traditional alkaline battery is not now so striking, especially when viewed against the need for high temperature operation, problems of reliability, safety, corrosion and so on. Moreover, it is estimated that the cost per kWh of these high temperature batteries will be similar to those of lead–acid and nickel–zinc; a desirable feature of an advanced battery would be reduced cost as well as improved performance.

Encouraging developments in basic scientific studies on solid-electrolyte synthesis and characterisation, and on solid–solution electrodes, do, however, promise that a new generation of advanced batteries may be possible without the disadvantages observed for sodium–sulphur and similar systems. Improved electrolytes, electrodes and electrochemical understanding of interfacial transport phenomena will, we hope, lead to cheaper, safer, and easier-to-construct second-generation advanced batteries.

The European basis for the new programme

Although much interesting work on new solid electrolytes has been undertaken in several scientific centres in Europe, there is little European industrial involvement so far with second generation ideas. Most of the interesting new developments and patents which might lead towards the second generation of advanced batteries have come from US industry. The example of the Li–TiS_2 battery has already been mentioned.

The Anglo–Danish programme aims to redress this imbalance. Although it will only run in the first instance for 18 months, to the middle of 1979, which is the end of the first 4-yr period of the European Commission's energy conservation programme, indications of success by this time may lead to a larger R & D role for advanced batteries in the next 4-yr programme. Industrial cooperation on promising developments will then be sought.

Although a European perspective for this programme, which is designed to lead to commercially exploitable products, involves a considerable re-orientation of attitude from the national perspective normally taken in such work, it is hoped that the wider view will lead to a better overall assessment of the commercial prospects for advanced battery systems.

The laboratories participating in the programme and the principal investigators, apart from the authors are: UKAEA Harwell Laboratory; Inorganic Chemistry Laboratory, Oxford University (Professor J. B. Goodenough); Department of Metallurgy and Materials Science, Imperial College London (Dr B. C. H. Steele); Department of Ceramics, Leeds University (Professor R. J. Brook); Odense University (Professor J. W. Perram); Danish Technical University, Lyngby (Dr K. Fl. Nielsen); Risø Laboratory (Dr O. Toft Sørensen).

The Allende meteorite: evidence for a new cosmothermometer based on Ti^{3+}/Ti^{4+}

Stephen E. Haggerty
Department of Geology, University of Massachusetts, Amherst, Massachusetts 01003

Applications of the mineral thermodynamic condensation sequence to assemblages in Ca–Al–Ti-rich inclusions in the Allende meteorite suggest that the total amount of titanium and Ti^{3+} *contents of aluminous clinopyroxenes (fassaites) are temperature sensitive and that the ratio* Ti^{3+}/Ti^{4+} *may be used as a qualitative cosmothermometer.*

THE Allende meteorite was an observed fall in Pueblo Allende, Mexico in 1969 and it is classified as a type 3 carbonaceous chondrite. This meteorite has received unprecedented attention because it contains a suite of mineral inclusions which are in agreement with the predicted equilibrium thermodynamic calculations for phases condensing at 10^{-3} atm in the solar nebula[1–4], and because these inclusions probably represent some of the most primitive high temperature condensates yet encountered[5–8]. The sequences of mineral condensates, as a function of temperature, are summarised in Table 1 and although there is now uniform agreement that these inclusions, which are rich in calcium, aluminium and titanium, are relics of the primordial nebula, it is still unresolved from the evidence provided by chemical[9–17], mineralogical[18–24], and isotopic data[25–29], whether condensation ensued directly from a nebular gas to the solid[3,4], whether condensation gave rise to a liquid before solidification[18], or whether the inclusions are the refractory residue of chondritic composition remaining after intense heating and volatilisation[30,31].

Formation of inclusions

The differences of opinion on the formation of these inclusions, as primary condensates or as crystallisation products from a melt, depend partly on the interpretation of whether or not equilibrium conditions prevailed during the nucleation of mineral species in the early solar nebula. If the predicted solar thermodynamic mineral condensation sequence is followed (Table 1) we may assume equilibrium, and the calculations are based on an assumption of equilibrium[1–4]. However, if the inclusions are derived by crystallisation from metastable and supercooled condensed liquids, the kinetics of refractory solid–solid reactions argue against a continuation of equilibrium to lower temperatures[18]. Provided a distinction is made between inclusions that have high temperature affinities, and inclusions that have lower thermal stabilities, the question of equilibrium is largely reconciled. Only high temperature assemblages are considered here and the thermodynamic model of direct condensation to a solid is favoured.

The refractory inclusions in the Allende meteorite contain a variety of minerals with high titanium concentrations, and evidence is presented here which demonstrates that the valency states of titanium (Ti^{3+} and Ti^{4+}) vary as a function of temperature. Based on the distribution and the abundance of titanium, and on the systematics of mineral assemblages that are predicted from the thermodynamic calculations, it is proposed that Ti^{4+} and Ti^{3+} may be useful as a potential, but as yet uncalibrated, condensation cosmothermometer.

From the minerals listed in Table 1 and shown in Fig. 1, the major titanium phases in Ca–Al-rich inclusions in the Allende meteorite are: hibonite ($CaAl_{12}O_{19}$), 1–10 wt% TiO_2; perovskite ($CaTiO_3$), 58 wt% TiO_2; rhonite, $Ca_4(Ca, Mg, Al, Ti)_{12}(Al, Si)_{12}O_{40}$, 12–22 wt% TiO_2; and titanian–fassaite (clinopyroxenes in the quaternary system $CaMgSi_2O_6$–$CaAl_2SiO_6$–$CaTi^{4+}Al_2O_6$–$CaAlTi^{3+}SiO_6$), 2–18 wt% TiO_2. Calculations of

Fig. 1 *a*, The ranges of condensation temperatures for minerals condensing at 10^{-3} atm in the solar nebula; these data are listed in Table 1 and are from Grossman[3] and Blander and Fuchs[18] *b*, The same condensation sequence as a function of Ti^{3+} Titanium-bearing minerals are perovskite, fassaite, Ti_2O_3, anosovite, TiO_{2-x}, and rutile. Initial condensation temperatures for perovskite and for rutile are labelled limits denoting the upper and lower limits of Ti^{4+} stabilisation, the intermediate range in temperature is the region of Ti^{3+} and Ti^{4+} stabilisation. The dashed curve labelled TiO_{2-x} are Magneli phases or anionic deficient rutiles which may exist in the transitory interval between $Ti^{3+}+Ti^{4+}$ stabilisation and Ti^{4+} stabilisation exclusively. The location of Ti_2O_3 is considered, but dismissed as the peak stabilisation for Ti^{3+}, see text. The dashed and solid curves labelled fassaite are two alternative trends for Ti^{3+} as a function of condensation temperature. The dashed curve is implied because it would provide a symmetrical Ti^{3+} distribution; however, the solid curve is applicable as demonstrated by fassaite-bearing inclusions in Allende with Ti^{3+} decreasing as a function of decreasing *T* K (see Fig. 2)

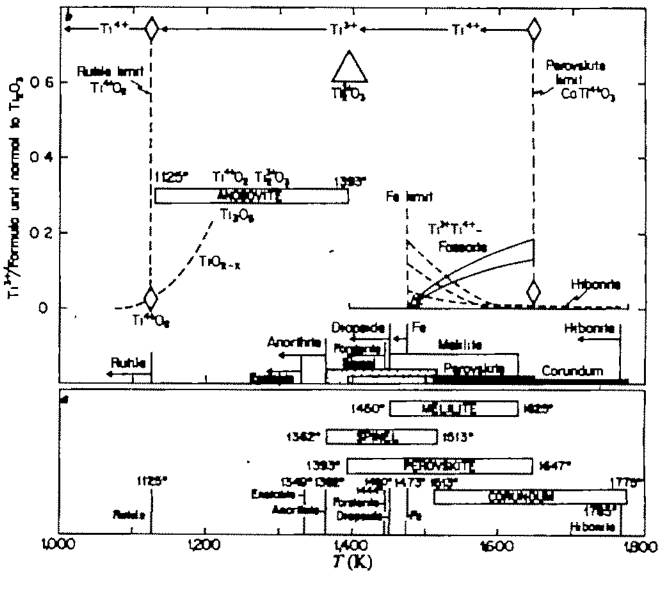

Table 1 The initial and final temperatures of condensation

Phase	Formula	Initial condensation temperature (K)	Temperature of disappearance (K)
Corundum	Al_2O_3	1,775	1,513*
Hibonite*	$CaAl_{12}O_{19}$	1,765	
Perovskite	$CaTiO_3$	1,647	1,393
Melilite	$Ca_2Al_2SiO_7$– $Ca_2MgSi_2O_7$	1,625	1,450
Spinel	$MgAl_2O_4$	1,513	1,362
Metallic iron	Fe(Fe–Ni)	1,473	
Diopside	$CaMgSi_2O_6$	1,450	
Forsterite	Mg_2SiO_4	1,444	
Anosovite	Ti_3O_5	1,393	1,125
Anorthite	$CaAl_2Si_2O_8$	1,362	
Enstatite	$MgSiO_3$	1,349	
Rutile	TiO_2	1,125	
Albite	$NaAlSi_3O_8$	~1,000	
Nepheline	$NaAlSiO_4$	~1,000	
Troilite	FeS	405	
Magnetite	Fe_3O_4	≤200	

Values taken from Grossman[3], except for * which are from Blander and Fuchs[18].

mineral composition data obtained from electron microprobe analyses, and based on the assumption of mineral stoichiometry, show that >95% of the titanium in perovskite is in the Ti^{4+} state, that ~10% of the Ti in hibonite is Ti^{3+}, that ~20% of the Ti in rhonite is Ti_2O_3, and that between 24 and 87% of the Ti in titanian–fassaite is also Ti^{3+}.

Thermodynamic considerations

Calculations for the predictive thermodynamic condensation sequence show that Ti^{4+} is stable in the mineral perovskite ($CaTiO_3$) at an initial temperature of 1,647 K; that Ti^{4+} and Ti^{3+} are stable in anosovite (Ti_3O_5) at an initial temperature of 1,393 K; and that Ti^{4+} is once again exclusively stable in rutile (TiO_2) at an initial condensation temperature of 1,125 K (refs 3, 4). This sequence of progressive stabilisation and destabilisation of Ti^{4+} is apparently, therefore, inconsistent with the widely held view that the condensing solar nebula becomes increasingly more oxidising with decreasing temperature. This is only an apparent anomaly because metallic titanium is stable at temperatures above perovskite. The interval between perovskite and rutile is in the interval of Ti^{3+} (and Ti^{4+}) stability, so that the presence of Ti^{3+} and the ratio of Ti^{3+}/Ti^{4+} should permit an estimate of the condensation temperature for the titanium-bearing minerals in that intermediate range which is constrained by the temperature limit of perovskite at the high end and by rutile at the lower end (Fig. 1).

To define the temperature range for the initial condensation of titanium-bearing minerals in the Allende meteorite the thermodynamic sequence must be rigorously followed and this sequence must be in agreement with the petrogenesis of the titanium-rich Ca–Al inclusions in Allende. Given these assumptions an analysis of the role of Ti^{3+} and Ti^{4+} in the condensation sequence now becomes possible. The absolute upper and lower limits of Ti^{4+} stabilisation are defined by perovskite (1,647 K) and by rutile (1,125 K), and values for intermediate Ti^{3+}/Ti^{4+} values are known for anosovite (Ti_3O_5 or $Ti^{4+}O_2$; $Ti_2^{3+}O_3$) to be in the range 1,393–1,125 K (refs 3, 4). Therefore, the peak stabilisation of Ti^{3+}, as $Ti_2^{3+}O_3$, ought to be above the upper limit of anosovite (1,393 K). Ti_2O_3 is therefore predictably stable between 1,647 K (perovskite) and 1,393 K (Fig. 1). If this peak stabilisation of Ti^{3+} is correct then the question arises as to whether the transformation of Ti^{4+} to Ti^{3+} is progressive on both the high temperature and low temperature sides of Ti_2O_3 (Fig. 1), or whether the transformation is abrupt. With respect to the low temperature side, the synthetic stable occurrences of non-stoichiometric rutile (TiO_{2-x}), known as Magneli phases[32–46] may be invoked, and the transition from anosovite to rutile may follow a smooth curve of progressively variable Ti^{3+}/Ti^{4+} concentrations at temperatures above 1,125 K (rutile) but below that of anosovite at 1,393 K (refs 47, 48). This proposed variation is shown in Fig. 1. The decrease towards Ti^{4+} stabilisation may also be applicable to the high temperature side of Ti_3O_5; however, an alternative is that the variation is simply a progressive decrease in Ti^{3+}, and in total titanium, in the range of condensation from perovskite to anosovite, that a peak in Ti_2O_3 is not attained and that both Ti^{3+} and Ti^{4+} are stable between 1,647 K (perovskite) and 1,125 K (rutile).

Discussion and results

To test these hypotheses the electron microprobe analyses of fassaites from the present study and from the literature[18–24,49] were recalculated assuming mineral stoichiometry, to determine the proportions of Ti^{3+} and Ti^{4+} in Allende pyroxenes. These

Fig. 2 Ti^{3+} plotted against total titanium for fassaites and associated pyroxenes and rhonite in inclusions 3898, All-4 and All-3,6. The data are derived from electron microprobe analyses with Ti^{3+} calculated, assuming mineral stoichiometry. ▲, Nos 1–15, and labelled *A–I* are from the literature listed in Table 2. ●, and the solid, slightly curved lines represent trends in zoned fassaites. Note that the rhonites are plotted on a reduced scale and in reality are at least a factor of two richer in Ti^{3+} than the associated fassaites. The horizontal tie-lines between rhonite and fassaite compositions are for rhonites that have decomposed to fassaite + perovskite + spinel. Open circles represent intra-crystalline fassaites. The dashed line marked ALL-4 is the overall trend for fassaite compositions (130 analyses) in this inclusion; these data are not plotted but are given in Haggerty and Merkel[47]. Arm, armalcolite, mineral 'T' to the new solid solution mineral; R_X, products of partial decomposition of mineral 'T' (ref. 53). Fassaites ions are based on 6 oxygens: rhonites are based on 40 oxygens (cation plot = 28/7).

Analyses as listed by Mason[49], and are from the following sources: *B*, *E*, and *H* from Gray *et al.*[7]; *C* from Clarke *et al.*[9]; *D* from Marvin *et al.*[6]; *F* from Dowty and Clark[50]; *G* and *I* from Fuchs[20]. Analyses listed numerically (1–16) are from Grossman[22].

* Cationic totals assuming that Ti total is TiO_2. Any deviation to values <4.0 suggests Ti^{3+}. Recalculated TiO_2, Ti_2O_3 and normalised formulae assume stoichiometry.

results are presented in Tables 2 and 3 and Fig. 2. Although the confidence levels in these calculations are perhaps no greater than 95% it is relevant that independent optical spectra data[50–52] have demonstrated that Ti^{3+} is present in Allende pyroxenes and that the ratio of Ti^{3+}/Ti^{4+} in the fassaite studied is equal to 0.72 (Table 2 analysis *F*). Particularly close attention was given to monitoring the Ti standard during the microprobe analyses of the present study and repeated analyses were carried out so that the results are not only internally consistent, but are also consistent with data obtained by eight other laboratories. Although the bulk mineralogy of the inclusions from the literature cannot be directly related to those from this study there is uniform agreement among the data that Ti^{3+} is a major component of titanian–fassaites in the Allende meteorite. The proportion of Ti^{3+} correlates positively with total Ti content; and negative and positive correlations exist between Ti^{3+} and Al, and between Ti^{3+} and Si, respectively. These data, although broadly comparable among inclusions, are clearly related to a variety of inclusions which may, or may not, represent precisely identical thermal condensation intervals (Fig. 2).

Fassaite data from three coarse-grained Ca–Al–Ti-rich inclusions (0.5–1.0 mm in diameter) from Allende are shown in Fig. 2 as a function of Ti^{3+} against Ti^{3+}/Ti^{4+}. These inclusions, designated 3898, All-4 and All-3,6, contain the following assemblages: inclusion 3898 has rhonite as the earliest formed mineral. Rhonite forms cores which are mantled by titanian–fassaite and these rhonites are partially decomposed to spinel + perovskite + titanian–fassaite. The other minerals present are melilite + spinel + hibonite + perovskite. Minute blebs of Fe–Ni alloys occur along cracks in the inclusion in association with grossular garnet, and these minerals are considered to be secondary or reaction condensation products. Inclusion All-4 has the assemblage melilite + titanian–fassaite + spinel + hibonite + perovskite. Inclusion All-3,6 has two contrasting assemblages: an interior assemblage of anorthite + forsterite + spinel + titanian–fassaite + armalcolite + perovskite + a new mineral series along the solid solution join $R^{2+}Ti_3^{4+}O_7$–$R_2^{3+}Ti_2^{4+}O_7$ (where R^{2+} = Ca, Mg, Mn, Fe; and R^{3+} = Ti^{3+}, Cr, Al); and an exterior assemblage of diopside + enstatite + pentlandite + troilite + Ni–Fe alloys (Fig. 2).

The titanium contents of the fassaites from these three inclusions fall into two populations: one that is high in titanium and a second that is somewhat lower in titanium. The rhonite within fassaite crystals contains the highest total Ti concentration and the highest Ti_2O_3 value (20 wt% Ti_2O_3). The associated fassaites are compositionally zoned, contain 16 wt% Ti_2O_3 at rhonite contacts and a minimum of 6 wt% Ti_2O_3 at fassaite crystal margins. Fassaites in inclusion All-4 have an average Ti_2O_3 content of 9.94 wt% (range, 8.1–14.4 wt%), and an average TiO_2 content of 4.92 wt% TiO_2 (range, 2.04–6.73 wt%), obtained from 125 electron microprobe analyses. These data lie along a relatively smooth curve as summarised in Fig. 2 and are distinguished from the data for inclusion 3898 which occupy a broad band in the distribution of Ti^{3+} and total titanium. Fassaites in the interior of inclusion All-3,6 range from 7 to 10 wt% Ti_2O_3 whereas those on the margins of the inclusion decrease progressively to <1 wt% Ti_2O_3.

The condensation temperature for diopside ($CaMgSi_2O_6$), a member of the multicomponent pyroxene system, is calculated to be 1,450 K. It is reasonable, therefore, to assume initially that the more complex pyroxenes are within the range of this value, but that higher condensation temperatures are to be expected because of the extraordinarily high T and Al concentrations. Several temperature constraints for titanian–fassaites become apparent if the mineralogies of the Allende inclusions are integrated into the thermodynamic condensation temperature model (Table 1). These are as follows: (1) titanian–fassaite is paragenetically earlier than melilite ($Ca_2Al_2SiO_7$–$Ca_2MgSi_2O_7$), which has a condensation temperature in the range 1,625–1,450 K, this defines an upper limit of >1,625 K; (2) spinel ($MgAl_2O_4$) overlaps paragenetically with titanian–fassaite so that although the melilite upper limit remains fixed, the spinel (1,513–1,362 K) lower limit of 1,362 K now becomes effective; (3) titanian–fassaites are also present in association with forsterite (initial condensation $T = 1,444$ K) and anorthite (initial condensation $T = 1,362$ K), but not with enstatite (initial condensation $T = 1,349$ K), and this distribution now moves the lower limit from 1,362 K (spinel) to 1,349 K. Condensation temperatures for titanian–fassaites, therefore, are considered to be in the range >1,625 K–1,349 K.

Assuming this temperature range, and in association with the mineral chemistries of the three inclusions (3,898, All-4 and All-3,6), relative temperatures of initial condensation may be estimated. Because rhonite has re-equilibrated to titanian–fassaite+spinel+perovskite in 3898, and because rhonite has the largest concentration of titanium and the highest proportional content of Ti^{3+}, it is assumed to have condensed at $T > 1,625$ K, but $T < 1,647$ K (initial condensation T K of perovskite). Rhonite may have condensed before perovskite but that cannot be unequivocally demonstrated. Inclusion All-4 is inferred to have condensed in the interval $T = 1,450$–$1,625$ K, based on melilite stability; it may have condensed at temperatures slightly higher than 1,625 K but not as high as 1,647 K, or as high as the rhonite-bearing inclusion 3898. The lower limit of condensation for inclusions 3898 and All-4 is defined by the condensation temperature of iron at 1,473 K. Neither of these inclusions have either metallic iron or FeO in mineral analyses and the terminal condensation temperature must, therefore, have been higher than 1,473 K. Inclusion All-3,6 is clearly a lower temperature condensate based on the assemblage anorthite+forsterite+diopside+enstatite (Table 1, Fig. 1), the presence of Ni–Fe alloys, and the presence of FeO in spinel, armalcolite, olivine, the new mineral series ($R^{2+}Ti_3^{4+}O_7$–$R_2^{3+}Ti_2^{4+}O_7$), and titanian–fassaite[53]. The upper limit of condensation, therefore, is $T < 1,473$ K, the initial condensation temperature of metallic iron. The lower limit for this inclusion is defined by enstatite, at the margins of the inclusion, at $T < 1,349$ K, but reaction continued in the condensing nebula to temperatures as low as 405 K (troilite) before incorporation into the carbonaceous matrix.

* Number of analyses averaged.

The complex but systematic decreases in zoned titanian–fassaites in inclusion 3898 (Fig. 2), the larger bulk titanium contents of fassaite at rhonite decomposition boundaries, and the relative displacements of fassaite titanium concentrations between inclusions characterised by melilite (3898 and All-4), and inclusions dominated by anorthite+forsterite (All-3,6), suggest that titanium dissolution in aluminium-bearing clinopyroxenes is temperature dependent and that these concentrations reflect the environment of solar nebula condensation. These data, therefore, show that total titanium and the proportion of Ti^{3+} decrease progressively with decreasing condensation temperature and that a peak in Ti^{3+} stabilisation, as the oxide Ti_2O_3, is not attained. The overall trends in Ti^{3+} distributions presented here may only be part of a more complex picture. Inclusions having melilite and anorthite, or inclusions in which the evolution of perovskite can be traced, are clearly required to provide information on the behaviour of Ti^{3+} at ~1,450 K (Fig. 2), and to establish whether the pyroxene trends are duplicated by other titanium bearing minerals.

Conclusions

I conclude that: (1) the calculated thermodynamic condensation mineral sequence is consistent with assemblages and compositions of phases in the high Ca–Al–Ti inclusions in the Allende meteorite; (2) because the predicted thermodynamic sequence is followed, the direct gas to solid condensation hypothesis is favoured; (3) based on these thermodynamic calculations the condensation interval of Ti^{3+} stabilisation is in the temperature range 1,647–1,125 K; (4) the Allende inclusion evidence and thermodynamic constraints suggest that titanian–fassaites condensed in the temperature interval defined by an upper limit of 1,625 K and a lower limit of 1,349 K; (5) the presence of Ti^{3+} in titanian–fassaites may be used as a qualitative cosmothermometer, with the ratio of $Ti^{3+}/Ti^{3+}+Ti^{4+}$ and total Ti content being high at high condensation temperatures and lower at correspondingly lower condenstion temperatures; and (6) rhonite-bearing inclusions have high initial condensation temperatures, which are followed by inclusions with titanian–fassaite and melilite, and these in turn are followed at lower temperatures by inclusions with anorthite+forsterite+diopside+enstatite, suggesting that the Allende meteorite has sampled a spectrum of the condensing solar nebula.

It is emphasised that the ranges of temperatures that are estimated for minerals in the Ca–Al–Ti rich inclusions in the Allende meteorite are subject to the limits of accuracy in the thermodynamic data. However, improvements to these data are unlikely to alter the overall conclusions, although the temperature estimates will undoubtedly be refined.

This study was supported by NASA. The electron microprobe facility was established under grants from the NSF and the University of Massachusetts. I thank L. Grossman, P. Robinson and G. A. Merkel for useful discussions, and G. Brophy for the loan of a sample of Allende from the Amherst College meteorite collection.

Actinide activities in water entering the northern North Sea

C. N. Murray* & H. Kautsky

Surface seawater measurements of $^{239+240}$Pu, ^{238}Pu, ^{241}Am and ^{137}Cs have been carried out in the North Sea and western Atlantic. Statistical analysis demonstrated that the discharges by fuel reprocessing plants in the UK are affecting plutonium activities in these sea areas. A difference in behaviour of americium to plutonium was also observed.

THE North Sea is a multi-use coastal-sea area of great economic importance to European countries. As a development of the data collection on actinide element distribution in this region, a detailed investigation was undertaken in July–September 1976 by the FS Meteor of the northern North Sea and Western Atlantic, northwards of 56°30′ N till 65°00′ N bounded by 10°00′ W to about 8°00′ E. Fifty-eight sampling stations were measured for surface water activity of $^{239+240}$Pu and ^{238}Pu; ^{241}Am measurements were carried out at 16 stations. Caesium, strontium, ruthenium and tritium measurements were also undertaken and will be reported elsewhere (H.K. in preparation).

The number of results obtained in these sea areas permitted a statistical analysis of $^{239+240}$Pu and ^{137}Cs data for variations in distribution, this was carried out for three different sea regions An initial estimate has been made of the dispersion of plutonium and the identification of its source as being other than from fallout determined.

Methods

Collection and analysis of actinides and caesium have been described in detail elsewhere[1,2]. These methods have been used on IAEA intercalibration samples and the results obtained compared with other laboratories by Murray and Stathan[1]. Sampling techniques and statistical treatment for these intercalibration samples are discussed in detail by Fukai and Murray[3].

The present sampling procedure, which measures the total actinides in unfiltered samples, was carried out on-board the FS Meteor. A series of samples, from two stations, were analysed on-board and in Hamburg to demonstrate that the precipitation carried out at sea and subsequent handling had no systematic effect on the results. No differences in the water activities obtained by the two methods could be detected. Monitoring of the chemical yield solutions before and after the cruise showed that no changes had occurred in their activity during the 2-month period.

The reproducibility of the method for both plutonium and americium was checked by taking replicate sets of samples at three stations, those at 58°36′ N, 02°52′ W; 58°30′ N, 05°29′ W

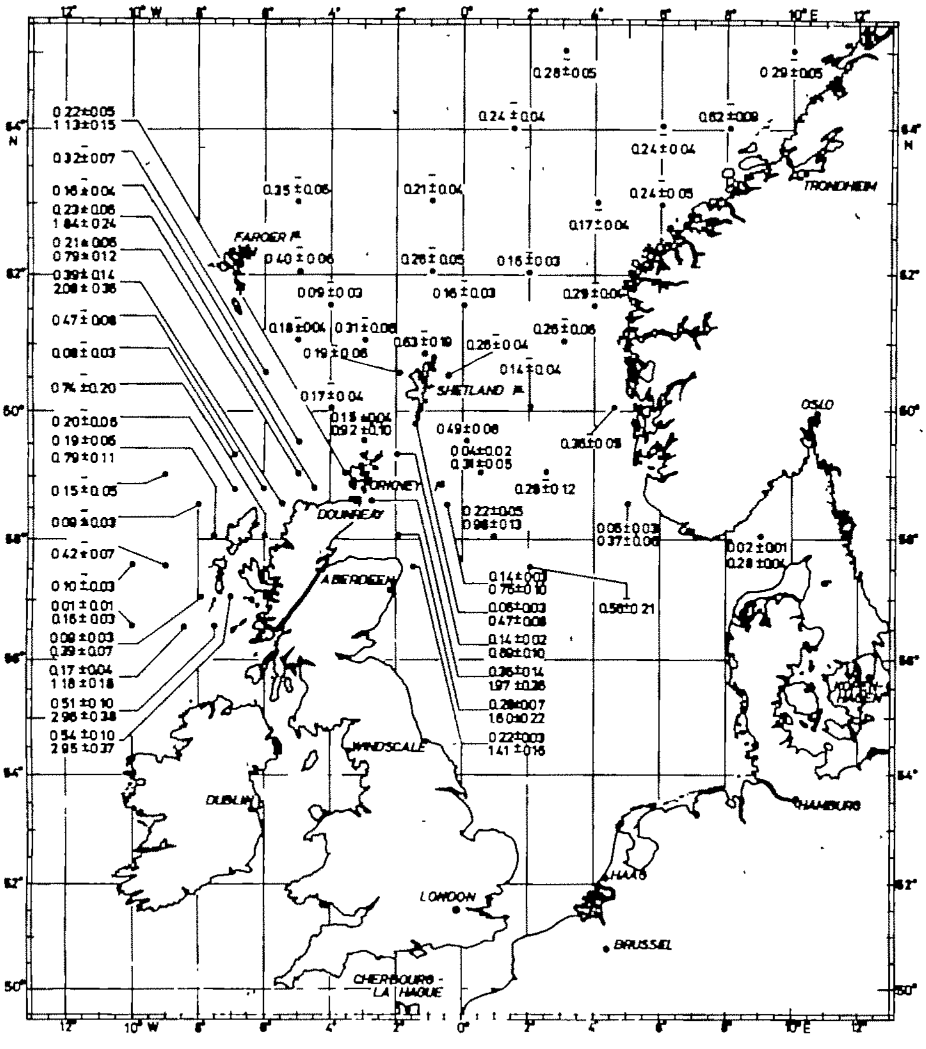

Fig. 1 ^{238}Pu, $^{239+240}$Pu: activity concentrations in Scottish coastal, North Sea and Atlantic surface waters (fCi kg^{-1}).

and 57°00′ N, 07°30′ W. One sigma (1σ) deviation from the mean values for $^{239+240}$Pu, ^{238}Pu and ^{241}Am, of three samples for plutonium and two samples for americium for each of three stations were ±14%, ±24% and ±28% at activity concentrations of the above isotopes of 2, 0.4 and 0.2 fCi kg^{-1} respectively. Results varied within the single sigma propagated error of the measurements. Reagent blanks were carried out regularly within the chemical separation scheme. All results are given with a 1σ propagated error.

Results and discussion

Figure 1 shows the surface water activity of $^{239+240}$Pu; values of ^{238}Pu are shown where they were measurable in the volumes analysed. Using the ratio $^{239+240}$Pu/^{137}Cs as a criterion for partitioning the sea area under investigation into regions of comparable ratios, three zones A, B and C were clearly distinguishable; these are shown in Fig. 2. Zone A comprises the Scottish and Norwegian coastal areas and the North Sea and has $^{239+240}$Pu/^{137}Cs ratios of $<0.5\times10^{-3}$; zone B, an intermediate area has ratios between 0.5 and 1.0×10^{-3}; and zone C, the Atlantic region, has ratios $>1.0\times10^{-3}$.

It is well documented[2,4,5] that increased ^{137}Cs activities measurable in the northern North Sea and along the east coast of the UK are due to the operation of the nuclear fuel reprocessing plants at Windscale and Dounreay.

The first increases in ^{137}Cs above fallout levels in water entering the southern North Sea through the English Channel were detected by Kautsky[2] in 1969, higher water concentrations being measured as far as the Belgian and Netherlands coastlines. The first indication in the northern North Sea was detected by Kautsky in 1971, along the northeastern coast of Scotland. Successive investigations carried out in 1971 and 1972 indicated that the caesium was being transported southwards along the east coast of England.

In water coming from the English Channel, Kautsky[2] observed that caesium was transported along the Holland and German Coasts. At this time very little northwards movement towards the southeastern coast of the UK was detected. By 1972 Kautsky[2] was able to show that some mixing of waters containing ^{137}Cs originating from UK and French fuel reprocessing plants took in the southern North Sea.

Studies by Murray and Eicke[6] in 1975 on actinide concentrations in sediment and water of the German Bight showed that they were of fallout origin, the ^{238}Pu/$^{239+240}$Pu ratio being 0.06±0.02. Data obtained from the English Channel region for 1975 Murray *et al.*[7] for ^{241}Pu showed that the apparent detectable limit of actinide intrusion into the southern North Sea, at this time originating from Cherbourg, seemed to lie around 52° N. Apparently, therefore, actinides in the northern North Sea area of the present study must be principally due to sources other than the French reprocessing plant.

Caesium concentrations in the eastern North Sea along the Danish and Norwegian coasts are probably due to mixing of waters containing ^{137}Cs originating from both UK and French reprocessing plants; however, in the central and northwestern North Sea the data of Kautsky[2,5] show that the ^{137}Cs concentrations depend most probably on the UK plants only.

Recent data by Livingston and Bowen[8] have shown that plutonium originating from Windscale is measurable in the waters and sediments of the Minch. Data have also been published by Murray and Kautsky[9] that show that increased levels of

$^{239+240}$Pu can also be measured in waters along the north-east coast of the UK and they proposed that these might also be due to the same source. In the present work, using the fact that the source of ^{137}Cs in these areas is known, statistical comparison of the plutonium and caesium data was undertaken to determine whether this source was also responsible for the actinide distribution measured in the North Sea.

Statistical considerations

The whole sea area under consideration has been divided into three major zones A,B,C shown in Fig. 2: the areas have been defined on the basis of the $^{239+240}$Pu/^{137}Cs ratio as has been previously mentioned. Because of the small number of measurements made along the Norwegian coast, the results of this region, which on the basis of its plutonium to caesium ratios belongs to zone A (Scottish coastal area and the North Sea) have not been included in the statistical analysis.

Zone A has been subdivided into two parts, west and north of the Scottish coast, and the North Sea; these are separated in Fig. 2 by a chain dotted line. For both sub-areas the relationship between $^{239+240}$Pu and ^{137}Cs is very close. As bivariate normal distributions of the data cannot be expected the rank correlation coefficient r_s (Spearman) has been taken as a measure of the closeness of the relationships. For the west and north areas of the Scottish coast, a rank correlation coefficient (r_s) of 0.95 ($\alpha < 0.001$) has been calculated; for the North Sea area the coefficient is 0.93 ($\alpha \ll 0.001$). For the intermediate area (zone B) a correlation coefficient for the relationship between $^{239+240}$Pu and ^{137}Cs of 0.78 ($\alpha < 0.005$) has been found; this is similar to that determined for stations in the Atlantic (zone C) lying south of 60°15′ N, of 0.74 ($\alpha < 0.05$). For stations in this zone lying north of this latitude a negative relationship has been estimated of −0.27 ($\alpha > 0.10$). Due to the fact that (except in the case of the North Sea area) there are tied ranks and/or samples of more than 10 pairs, the reliability of the coefficients could be only approximately determined (see ref. 10).

Judging by the nearly equal and high correlation coefficients in the two sub-divisions of zone A, it may be concluded that a major source not only of ^{137}Cs but also of $^{239+240}$Pu in these areas is the discharge of low level radioactive waste from nuclear fuel reprocessing plants in the UK; the major activity coming from the Windscale discharge (some thousands of curies) with less than 5 Ci Pu y^{-1} coming from Dounreay. The contribution of the French plant to the ^{137}Cs concentration in these areas (other than the eastern areas of the northern North Sea) is considered to be small in comparison to the UK discharges. Adjacent areas of the Atlantic also seem to be affected by the UK releases.

Further data supporting the fact that the distribution of both isotopes can be accounted for by a similar mechanism of dispersion and source, even though ^{137}Cs is in a soluble cationic form and plutonium supposedly as an insoluble poly-hydroxy-complex, were obtained using the fact that ^{238}Pu activity could also be measured in Scottish coastal and North Sea waters. Figure 3 shows the activity concentration ratios of ^{238}Pu to $^{239+240}$Pu. Visual examination of the data showed clearly that there was a strong correlation between the isotope concentrations; the rank correlation coefficient was found to be 0.96 ($\alpha < 0.001$) and thus confirmed the relationship.

To estimate the ratio ^{238}Pu/$^{239+240}$Pu a regression line of the data (Fig. 4) from the regions was calculated by the method of least squares. The resulting equation $y = 0.1756x - 0.0007$

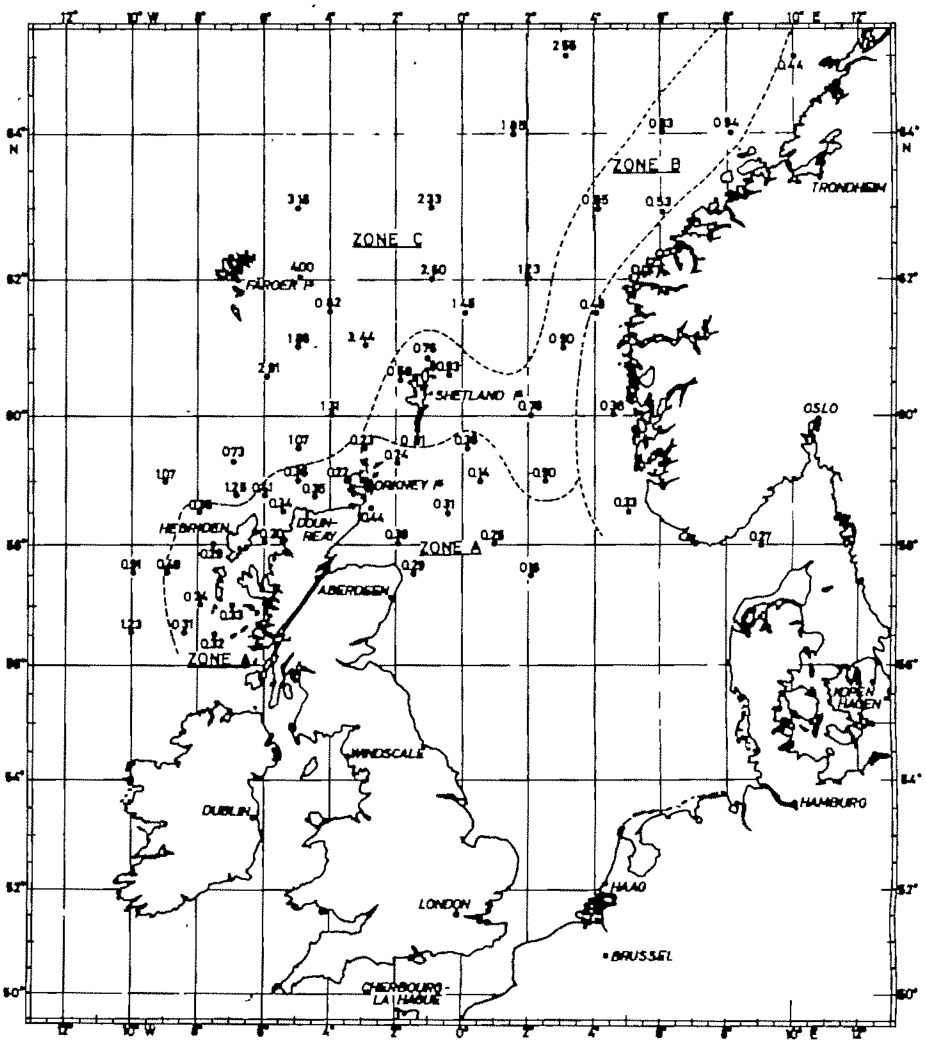

Fig. 2 Activity concentration ratios of $^{239+240}$Pu/^{137}Cs multiplied 10^3 in Scottish coastal, North Sea and Atlantic surface waters.

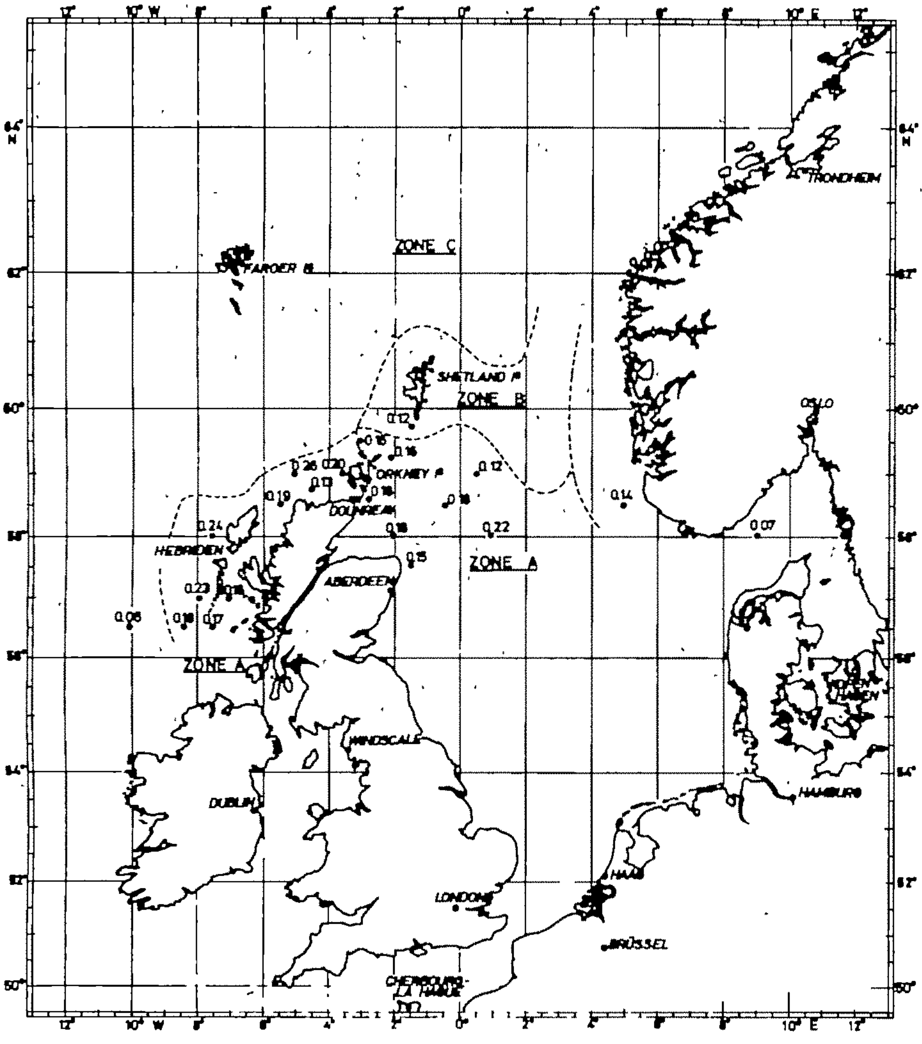

Fig. 3 Activity concentration ratios of ^{238}Pu/$^{239+240}$Pu in Scottish coastal, North Sea and Atlantic surface waters.

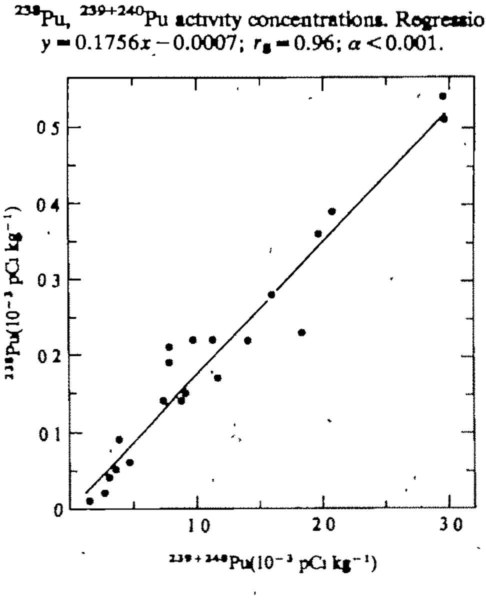
indicates that the regression line, as expected, goes through the origin. As both variables are subject to error the regression coefficient is distorted downwards. Estimated propagated errors have been used to calculate the correction factor for the regression coefficient according to the procedure proposed by Snedecor and Cochran[11]; the corrected coefficient was found to be 0.1797. As can be recognised, the downward bias is small. The 99% confidence limits of the regression coefficient have been estimated to be 0.1465 and 0.2129; the estimated ratio therefore of ^{238}Pu/$^{239+240}$Pu in Scottish coastal and North Sea waters is 0.18 with 99% confidence limits of 0.15 and 0.21 and is significantly different from the ratio of 0.066 ± 0.008 (1σ limits propagated error, figures calculated from data of Fukai *et al.*[12]) found for samples contaminated only from fallout plutonium in the Northern Hemisphere. Hardy *et al.*[13] report ratio results ^{238}Pu/$^{239+240}$Pu of about 0.04 for integrated samples (undisturbed soils) from the Northern Hemisphere 1970–71; the standard deviation of the average ratio being ±12%. At the 2σ level the ratios given in refs 12, 13 are indistinguishable and are significantly different from the ratios found in this present study.

Fig. 4 ^{238}Pu, $^{239+240}$Pu activity concentrations. Regression line: $y = 0.1756x - 0.0007$; $r_s = 0.96$; $\alpha < 0.001$.



It may be concluded that, as with ^{137}Cs, quantities of plutonium originating from the discharge of waste from nuclear fuel reprocessing plants into UK coastal waters are present in surface waters of the central North Sea and thus have been transported over large distances from their source of origin. An estimate of 1.1–1.8 yr for the transit time of ^{137}Cs from the vicinity of Windscale to the North Channel of the Irish Sea has been made by Jefferies *et al.*[4] for 1970–72. Two years has been estimated for the Minch by Livingston and Bowen[8]. The time required for its transport along the west and north Scottish coasts and into the North Sea is difficult to estimate, but if one takes an interval of a further 1.5–2.0 yr to pass through the Pentland Firth into the North Sea, this would mean that activities now being measured in the North Sea probably originated from discharges taking place during 1972–73 in the Irish Sea. This seems to coincide with an increased discharge by Windscale of α-containing low level waste that occurred at this time[14]. Thereafter discharges apparently decreased, according to data from Hetherington *et al.*[15,16].

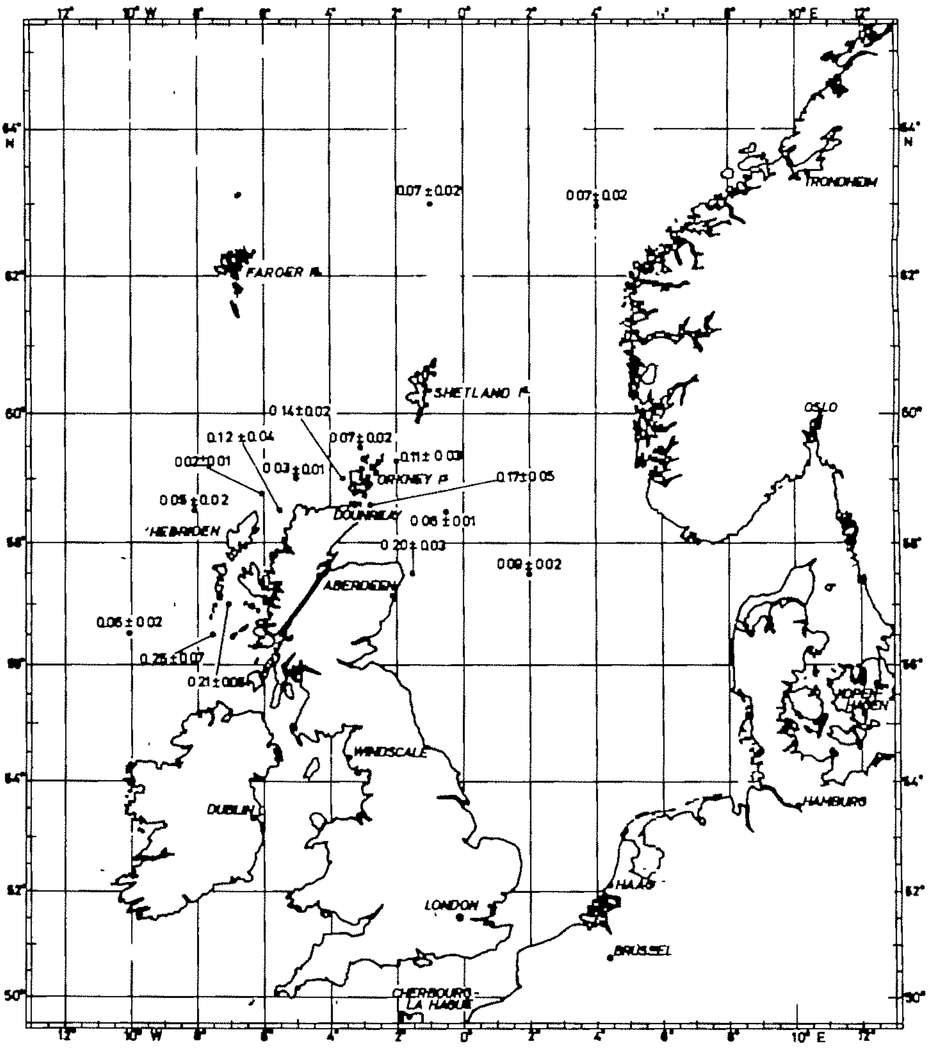


Fig. 5 ^{241}Am activity concentrations in Scottish coastal, North Sea and Atlantic surface waters (fCi kg^{-1}).

Figure 5 shows the measured activity levels of ^{241}Am in surface waters. It can immediately be seen that activities near the northwestern coast of Scotland are considerably smaller than those of plutonium; the ratio ^{241}Am/$^{238,239+240}$Pu for three stations between Barra to the Pentland Firth is only 0.06 ± 0.02. If we assume that the present results for activities in western Scottish coastal waters some 300–500 km north of Windscale are representative of discharges into the Irish Sea that occurred some 2.0–2.5 yr earlier, then this water was most probably contaminated some time in 1973–74. That these present ratios should be so small is surprising in view of the report by Hetherington *et al.*[17] who gave the Am/Pu α-radioactivity discharge from Windscale for 1971–74 as varying between 0.9 and 2.56. It seems that there has been a decrease in the ratio from about 1.7 at Windscale (average value 1971–74) to 0.06 some 300–500 km northwards along the Scottish coast. This decrease takes place in spite of the increase of ^{241}Am that will have occurred during its transport due to the decay of ^{241}Pu.

Our hypothesis that americium disappears more quickly from surface waters than plutonium is supported by data of Hetherington and Harvey[18] on the distribution of these elements between suspended material and solution in Irish Sea surface water. These workers reported that at a distance <10 km from the point of discharge, the percentage fraction of activity associated with suspended material for plutonium and americium was 36 ± 8 and 80 ± 7, respectively. The total activity in the water was found to be 2.4 ± 0.8 and 1.7 ± 0.8 pCi l^{-1} for the two isotopes. Thus at a distance of only 10 km from Windscale twice as much americium is associated with suspended material as plutonium; even at a distance of about 100 km this fraction is still more than 50%. The settling out of suspended particles from surface water thus tends to decrease the americium activity more quickly than plutonium.

In the present survey no measurable quantities of ^{242}Cm were detected in samples near the Scottish coast even though the chemical separation scheme we used is capable of detecting it at the same levels as for americium. Although the lack of ^{242}Cm activity in water could be due to the low concentrations discharged into the Irish Sea, Hetherington *et al.*[16] report it at levels similar to ^{238}Pu in the seaweed porphyra collected from the Cumberland coast. The fact that ^{242}Cm was not detected in Scottish coastal samples although apparantly present in water off the Cumbrian coast probably reflects the short half-life ($t_{1/2}$ = 163 d) of this isotope compared to the time taken for the water to travel that far north. The non-detection of curium is, however, also consistent with data obtained from the English Channel (C.N.M., unpublished data), which indicates that curium activity seems to be also lost more quickly from the water column than plutonium.

Conclusions

First, based on a statistical analysis of the distribution of ^{137}Cs and plutonium from samples obtained in July–September 1976, it has been shown that a significant fraction of surface water activity of plutonium in UK eastern coastal waters and the central North Sea originates from fuel reprocessing plants in the UK, the major contributor being Windscale.

Second, the fact that plutonium moves over such relatively great distances, although representing only a small fraction of that which is initially absorbed to bottom sediments, may have important consequences for considerations of its medium and long-term behaviour in the marine environment, especially in relation to the possible future siting of fuel reprocessing plants in North Sea coastal areas.

Finally, the apparent variations in the distribution of actinide isotopes in seawater, as shown in the present survey, underline the need for care in drawing conclusions about their environmental behaviour on the basis of a simple comparison with plutonium. The possibility of differences in behaviour for actinides coming from different sources must always be considered, when predicting their impact on the environment.

We thank J. Marschall for drawing the figures.

Surface antibodies of human myelogenous leukaemia leukocytes reactive with specific type-C viral reverse transcriptases

Paul C. Jacquemin, Carl Saxinger & Robert C. Gallo
National Cancer Institute, National Institutes of Health, Laboratory of Tumor Cell Biology, Bethesda, Maryland 20014

Purified immunoglobin G (IgG) from patients with chronic myelogenous leukaemia specifically neutralised RT from feline leukaemia virus while purified IgG from other types of leukaemias and from normal blood cells were less reactive and in some cases preferentially reacted with RT from horizontally transmitted primate type-C viruses (simian sarcoma virus–gibbon ape leukaemia virus group). This indicates the presence of a heterogeneous immune response to RT or to an RT-like molecule in humans.

SOME human leukaemic cells contain a cytoplasmic DNA polymerase similar to reverse transcriptase (RT) of RNA tumour viruses[1,2]. In some cases the enzyme has been partially purified[1,3,4]. Molecular weight, column elution, response to various template-primers and immunological tests distinguish RT from cellular DNA polymerases (α, β and γ)[1,3–8] and show its similarity to viral RT[1,3,4]. The activities of some partially purified, RT-like DNA polymerases from patients with acute myelogenous leukaemia (AML) have been specifically neutralised by IgG from hyperimmune sera prepared against RT from the simian sarcoma virus (SSV)–gibbon ape leukaemia virus (GaLV) group[3,9–12]. RT-like DNA polymerase neutralised by antisera against RT from SSV was also isolated from the spleen of a child with myelofibrosis[13] (a preleukaemic disease), who later developed AML. These results suggest that the enzymes from some AML cells and some preleukaemic cells are immunologically related to RT from these viruses Other RT-like DNA polymerases detected in human leukaemic cells were not detectably related to RT from any of the viruses studied, that is, SSV, GaLV, murine leukaemia virus (MuLV) and avian myeloblastosis virus (AMV) (refs 11, 12).

Some reports suggest expression of type-C virus-related structural proteins in human tissues (reviewed in ref. 12) and of antibodies reactive with them[14–16], but there are no reports of such interactions with purified proteins. It would be interesting to know whether antibodies to specific RTs can be identified in humans not only because of the RT-related polymerases but also because RT can be identified unambiguously by its function. We have not found anti-RT activity in human sera (unpublished results) in contrast to published results with two cases of AML[17].

We report here that the surface of some fresh human blood cells contains IgGs specifically reactive with certain viral RTs. The rationale for our experiments was (1) evidence for both the presence of a RT-like DNA polymerase in some leukaemic cells and the absence of detectable antibody to RT in human sera; (2) the precedent in solid tumours for tumour bound antibody[18] which can be eluted and isolated[19]; (3) indications of antibody on the surface of human leukaemic cells, the specific reactivity of which had not been elucidated[20,21]; and (4) indications that antibodies to RT may be present in some naturally infected cats[22], gibbons[23] and cows[24].

Detection and isolation of surface bound immunoglobulins

Leukocytes were obtained from whole blood from leukaemic or normal people by leukaphoresis or from the buffy coat of 500 ml of anticoagulated blood (acid citrate dextrose). The cells were maintained in a fresh, viable state at 4 °C during transport and washed three times at 4 °C with 10 vol. cold RPMI 1640 medium on receipt in our laboratory. They were assayed for surface Ig by measuring the binding of ^{125}I-labelled (ref. 25) F(ab')$_2$ fragments[26,27] of goat anti-human (GAH) IgG. In saturating conditions this amounted to 0.2–10 µg per 10^6 leukocytes from leukaemic donors and 0.05–0.2 µg per 10^6 leukocytes from normal donors.

The cell surface Ig could be eluted into serum-free media. The complexes formed between surface Ig and the ^{125}I-labelled GAH–IgG remained cell-bound during incubation at 4 °C overnight but were released by incubation at 37 °C in serum-free medium for 12–16 h as described by Witz[19]. The Ig detected on the surface of leukocytes was eluted from washed cells as described in the legend to Fig. 1. IgG was determined by a solid phase immunofluorescent assay (Biorad). The amounts of IgG recovered in the medium were similar to that detected on the intact cell surface by the binding assay. These findings are similar to results reported after acid treatment of leukaemic blood cells[20,21].

The Ig contained in the eluates from AML, chronic myelogenous leukaemia (CML), or normal blood leukocytes were purified as described in the legend to Fig. 1 and analysed at each step of purification by SDS polyacrylamide gel electrophoresis (PAGE). The stained gels from the crude eluates showed 5 to 10 bands, including two constituents with mobilities identical to control standard human IgG heavy and light chains. After immunoaffinity column chromatography the purified IgG on SDS PAGE revealed only two bands corresponding to heavy and light chains of IgG (not shown). The activity of the purified IgG fractions was stable at 56 °C for 1 h, non-dialysable, and not bound to DEAE-Agarose in 20 mM Na phosphate buffer, *p*H 8.

Inhibition of RT by IgG from CML leukocytes

The purified IgG was tested for inhibition of cellular DNA polymerases α, β, γ and terminal deoxyribonucleotidyl transferase (TDT), purified as before[5–8,28] from normal or leukaemic human leukocytes and for inhibition of RT purified[29,30] from various oncornaviruses. We used purified IgG because the magnitude and specificity of inhibition was greater than with the crude eluates, which contained competing proteins and protease artefacts. Cell surface IgG purified from the blood leukocytes of patients with the acute blast crisis (BC) phase of CML completely inhibited RT purified from some mammalian type-C viruses, most notably feline leukaemia virus (FeLV) (Fig. 1, Tables 1 and 2). Low concentrations of IgG were effective, for example, 50% neutralisation of FeLV RT was obtained with <0.2 μg using IgG from patient HL68 (Fig. 1*a–c*, Table 1). Table 1 shows that activity of the human cell surface anti-RT IgG compares quite favourably in specific activity with anti-RT IgG obtained from serum from animals immunised with RT or serum obtained from naturally infected animals. Furthermore, the inhibition was specific. There was no inhibition of cellular DNA polymerases α, β, γ or of TDT (Fig. 1*a*), nor of RT purified from avian type-C viruses or of RT from non-type-C retroviruses (Fig. 1*b*). Inhibition was found only with RT purified from some mammalian type-C viruses (Fig. 1*c*), especially FeLV (Fig. 1*a–c*). Blood leukocytes from eight of nine patients with CML-BC yielded antibodies with activity specifically against FeLV (Table 2). There was variation in the amount of cross-reactivity with RT from viruses related to FeLV. IgG from some patients showed remarkable type

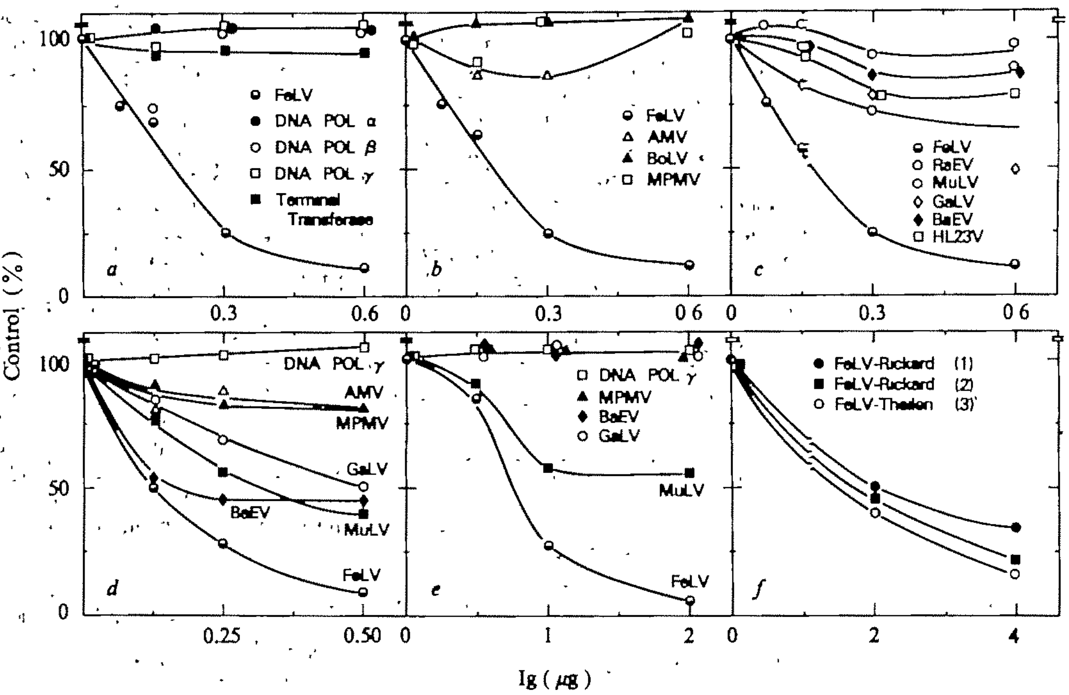

Fig. 1 Specific neutralisation of viral RT by IgG purified from blood leukocytes of patients with CML, blast crisis IgG was purified as follows. 10 g of washed blood leukocytes, obtained by leukaphoresis from patient (HL-68) with CML (BC), were incubated for 12 h at 37 °C in serum-free RPMI 1640 medium (10^7 cell ml^{-1}) containing gentamycin (50 μg ml^{-1}) and fungizone (2.5 μg ml^{-1}) to elute membrane-bound IgG. Some proteins in the eluate, including IgG, were precipitated by adding $(NH_4)_2SO_4$ to a final concentration of 50% The precipitate was dissolved in 20 mM Na phosphate, *p*H 8.0, then dialysed overnight against the same buffer An aliquot of the dialysed sample was analysed by SDS PAGE The IgG in the remaining sample, containing 4 5 mg of protein, was further purified on a DEAE Agarose column (10 mg protein per ml gel) The flow-through and 2 one-column vol washes of 20 mM Na phosphate, *p*H 8.0, were combined (total protein 1.7 mg) and further purified on an affinity column of Sepharose 4B specific for human IgG. The column was prepared as follows. Purified GAH IgG was coupled to cyanogen bromide activated Sepharose (Pharmacia in 0.1 M Na phosphate, *p*H 8.0, at a ratio of 10 mg IgG per ml 'swollen' gel The reactive groups were blocked with 0.5 M ethanolamine, *p*H 9 0, washed with 0 85% NaCl and equilibrated in solution A (0 05 M Tris–HCl, *p*H 7.4, 0.3 M NaCl containing 2% Triton X-100, 0.1% Tween 80, and BSA 10 mg ml^{-1}) One-third of the total protein of the commercial GAH IgG was specific for human IgG. Protein (1 7 mg), containing the IgG antibodies, obtained from the DEAE Agarose step was dissolved in 1 ml of solution A containing the affinity beads and incubated overnight at 0 °C. The slurry was then poured into a column, extensively washed with 0.85% NaCl until the A_{280} was < 0.01 Bound IgG was eluted with 0.2 M glycine, *p*H 2.8 and one ml fractions were collected at 4 °C. Different DNA polymerases were tested against IgG purified on DEAE Agarose and affinity chromatography. The 100% activity corresponds to activity of the different polymerases in the absence of antibody *a–c*, Purified IgG from patient HL-63, *d*, patient HL-105, *e*, *f*, patient HL-70. The IgG from patient HL-70 (*e*, *f*) were from two different preparations of purified IgG. *f* shows that RT purified from different strains of FeLV and/or by different methods are comparably neutralised by the IgG RT was purified from FeLV Rickard (1) by DEAE cellulose, phosphocellulose, poly G Agarose, and hydroxyapatite sequential column chromatography[30]. Purification of RT from FeLV Rickard (2) and for FeLV Theilen (3) was as previously described[29]. DNA polymerase (refs 5–7, respectively) and TDT[28] were purified from human leukocytes as described. FeLV (Rickard strain) was grown in feline lymphoid cells, F422; FeLV (Theilen strain) was grown in FL74 feline lymphoid cells; and various FeLV subgroups were also grown in NC37 human lymphoblasts and in canine thymus fibroblasts (FCf_2Th) AMV was obtained from chicken plasma. Other viruses are BoLV (bovine leukaemia virus) grown in sheep fibroblasts; MPMV (Mason–Pfizer monkey virus) grown in NC37 human lymphoblasts, RaEV (Rat endogenous virus) grown in Wistar rat cells; MuLV (AKR) grown in 3T3 mouse cells; GaLV (San Francisco strain), grown in NC37 cells; BaEV, grown in canine thymus cells (FCf_2Th) and in NC37 human lymphoblasts; and HL23V, a virus isolated from a woman with AML which predominantly contains a virus highly related to SSV and less of a second virus highly related to BaEV, grown in FCf_2Th cells RT were purified from different viruses after disruption in a 0 6 M KCl, 0 5% Triton X-100 by successive chromatography on DEAE cellulose, phosphocellulose, poly G Agarose and hydroxyapatite. In some cases an additional glycerol-gradient step completed purification. Details of these and alternative methods are described elsewhere[29,30]. Assays were in 0.05 M Tris–HCl buffer, *p*H 7 4 containing 140 μM ^{3}H-dTTP (3.6 Ci mmol^{-1}), 130 μM dATP, 50 μg per ml dT_{12-18} · poly A; 0.5 mM $MnCl_2$; 5.0 mM DTT; and 130 mM NaCl for all viruses with the following exceptions for AMV RT, 6 mM $MgCl_2$ was substituted for $MnCl_2$; for BoLV and MPMV RT the conditions were 50 μM ^{3}H-dTTP (10 Ci mmol^{-1}), 190 μM dATP and 40 μg per ml dT_{12-18} poly A Activities were measured at 30 °C for 30 min except for AMV, BoLV and MPMV, which were assayed at 37 °C for 30 min The enzyme and antibody were preincubated at 4 °C for 4 h in the preincubation buffer (0.05 M Tris–HCl, pH 7.4 with 130 or 190 mM NaCl, 2% Triton X-100, 10 mg per ml BSA, and 0.1% Tween 80) and then assayed as described above The 100% activity was obtained in the absence of antibody and varied between 40,000 and 70,000 c.p.m. (20–40 pmol) of ^{3}H-dTMP incorporated into acid-insoluble precipitates Comparable amounts of protein and enzyme units were used for each polymerase

Table 1 Comparison of neutralisation of cellular and viral DNA polymerases by different antibody (IgG) preparations

* Cellular DNA polymerase (pol) γ was a 9,000-fold purified enzyme from human lymphoblasts. Similar results were obtained with DNA polymerases α, β, γ and TDT. Viral polymerases (RT) were purified as described elsewhere[29,30]. Assay conditions are described in legend to Fig. 1.

† See text and legend to Fig. 1 for IgG purification procedure.

‡ Natural antibodies eluted from human CML blast crisis, AML, and normal blood leukocytes.

§ IgG purified from hyperimmune rabbit sera obtained after inoculation of animals with purified RT from Rauscher MuLV or GaLV.

‖ IgG containing specific anti-FeLV RT activity was purified from serum derived from a cat naturally infected with FeLV

specificity for FeLV with little or no reactivity against RT from other viruses, for example, IgG from patient HL-68 (Fig. 1*c*), while IgG purified from leukocytes of other patients with CML (BC) included cross-reactivity with RT from rodent type-C viruses (patient HL-70, Fig. 1*e*) or more extensive cross-reactivity (patient HL-105, Fig. 1*d*). RT purified by different methods and from different strains (Rickard and Theilen) of FeLV were comparably neutralised by IgG from patient HL-70 (Fig. 1*f*). Therefore, the specificity in polymerase neutralisation is probably not affected by variation in specific enzyme activity among different enzyme preparations. Also, RT from FeLV grown in several different types of cells (see legend to Fig. 1) was comparably neutralised by this IgG which indicates that cellular components do not influence the specificity of the interaction.

Three separate serial blood samples were studied from patients HL-62, HL-68 and HL-101 with relatively constant clinical and haematological features. The amount of IgG required to neutralise RT and the specificity pattern for anti-RT activity were constant. Six separate IgG purifications from one blood sample (patient HL-105) and multiple purifications from others also yielded reproducible results (data not shown).

Leukocytes from CML patients in remission (two cases) were negative or contained low levels of IgG not reactive with RT. Of four patients tested with CML in the chronic phase of the disease two were negative and two contained IgG with some inhibition of RT from the GaLV-SSV group (Table 2), especially the San Francisco strain of GaLV ($GaLV_{SF}$). The IgG most reactive with FeLV RT have been predominantly from a particular type and phase of leukaemia, namely Philadelphia chromosome-positive CML-BC lacking TDT. TDT, an enzyme generally found only in certain types of lymphoblasts[31–33] was discovered in CML-BC cells[28] and subsequently found in about one-third of these patients[33], indicating that these patients may develop an acute lymphoblastic proliferation in contrast to the usual myeloblastic proliferation. The IgG with activity against FeLV RT described here appears then to be associated mainly with CML-BC with acute myeloblastic proliferation.

Table 2 Summary of human blood leukocyte surface IgG with anti-RT activity

		Anti-RT activity	
Diagnosis and disease stage	Number studied	Number positive	Specificity of inhibition†
Leukaemic samples			
CML, blast crisis*	9	8	FeLV
CML, chronic phase*	4	2	$GaLV_{SF}$
CML, remission*	2	0	—
AML, untreated	5	2	SSV (and HL23V)
AMML, untreated	4	1	SSV (and HL23V)
AUL, untreated	2	0	—
Uncertain diagnosis (AML or CML crisis)	1	1	SSV (and HL23V)
ALL	3	0	—
CLL	3	0	—
Normal samples			
PHA stimulated blood lymphocytes (pooled 12 donors)	1	0	—
Bone marrow	4	1	$GaLV_{SF}$
Buffy coat blood leukocytes	24	7	$GaLV_{SF}$

* All CML patients were Philadelphia chromosome positive. Cells from those patients in blast crisis were negative for TDT assayed as described elsewhere[28,33].

† Positive cases were those in which the RT neutralisation titration showed ≥30% inhibition and no inhibition of control enzymes (control enzymes: see Fig 1*a*, *b*)

IgG from other leukaemic and from normal leukocytes

IgG were also purified from the surface of blood leukocytes from other types of leukaemia. Antibodies reactive with RT were obtained from two of five patients with AML and one of four acute myelomonocytic leukaemia (AMML) patients (Table 2). In general, the IgGs purified from the positive AML and AMML patients mainly inhibited RT from SSV or the SSV-related virus, HL23V[34]. This was shown with intact IgG (not shown) as well as with a $F(ab')_2$ fragment derived from the purified IgG (Fig. 2*a*). The amount of IgG required to inhibit the preferred RT by 50% was much higher (5 μg) than from patients with CML-BC. There was little or no inhibition of cellular DNA polymerases or of RT from AMV, baboon endogenous virus (BaEV), GaLV, MuLV or FeLV (Fig. 2*a*, Tables 1 and 2). Similar specificity patterns were also obtained with IgG isolated from a blood sample of patient (HL-67) with an uncertain diagnosis (AML or CML-BC). The inhibition of RT by this IgG was specific for SSV and HL23V polymerases (Table 2). We also examined two cases of acute undifferentiated leukaemia (AUL), three cases of acute lymphoblastic leukaemia (ALL), and three cases of chronic lymphocytic leukaemia (CLL) for IgG with anti-RT activity—all were negative (Table 2).

There is no natural source of tissue that provides comparable control cells for human leukaemic blast cells. By using techniques described for leukaemic blood cells, we prepared eluates from various established tissue culture cell lines, for example, bat lung fibroblasts and canine thymus cells and from diverse normal human haematopoietic cells, including peripheral blood buffy coat (24 donors), bone marrow samples (4 donors) and nylon column purified PHA stimulated blood lymphocytes (pooled from 12 donors) from normal individuals. None of the tissue culture cells or the cultured human blood lymphocyte eluates contained RT inhibitory activity, but 8 of 29 fresh normal human haematopoietic cell samples exhibited significant inhibitory activity for RT from mammalian type-C viruses, particularly RT from GaLV$_{SF}$ (>40% inhibition with 5 μg of IgG). All positive results were obtained with bone marrow or with buffy coat leukocytes (Table 2). Two typical examples are shown in Fig. 2*b* and *c*. Although RT from GaLV, and SSV are known to be closely related, the IgG from normal donors and from some AML samples (Table 1) distinguished them. At antibody concentrations of 2–5 μg RT from GaLV was inhibited from 50% to 80% while RTs from SSV and HL23V were inhibited less than 20%.

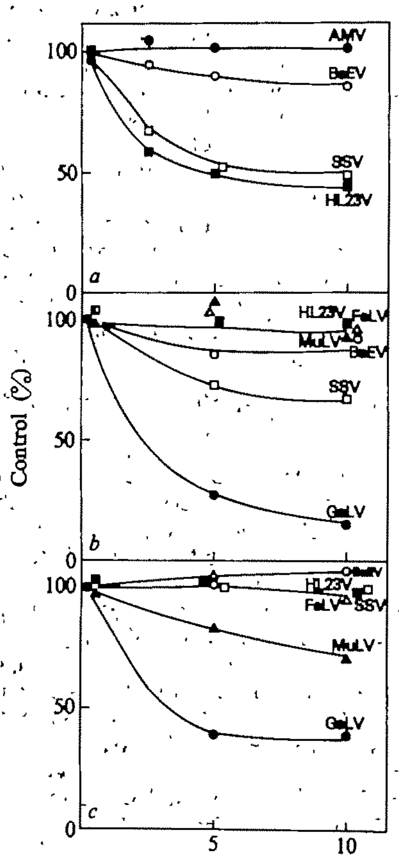

Fig. 2 Inhibition of RT purified from primate type-C viruses (SSV, GaLV, HL23V) by IgG from AML and normal leukocytes. *a*, Antibody from AML patient DEAE Agarose-purified IgG fraction from leukocyte eluates of patient HL-80 with AML was treated overnight with pepsin bound to Sepharose beads in 0.2 M NaAC buffer, *p*H 3.5. The pepsin fragments were purified on an affinity column of GAH IgG (light chain specific) The purified AML F(ab′)$_2$ fragments were then tested for inhibition of various polymerases. Cellular DNA polymerases were not inhibited (data not shown) *b*, and *c*, antibody from normal blood leukocytes DEAE Agarose-purified IgG fractions from eluates of blood leukocytes from two different normal donors were tested against different polymerases as described in text and legend to Fig. 1. Cellular DNA polymerases were not inhibited (data not shown).

Inhibition of RT is antibody mediated

Evidence indicates that the inhibitor of RT in eluates from some human leukocytes is a specific antibody and that the reaction studied is an antigen–antibody interaction. This evidence includes the biochemical and physical properties of the most active fraction, the specificity of inhibition of polymerisation reactions, the removal of known nonspecific inhibitors of these reactions and assays based on factors other than inhibition of enzyme activity. These are summarised below and in the following section.

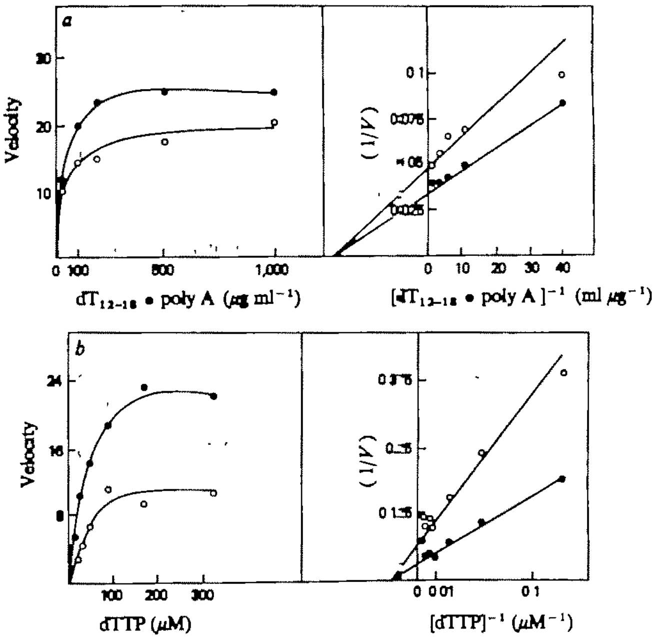

Fig. 3 Kinetics of inhibition of RT by purified IgG obtained from eluates of CML blast crisis cells (Patient HL-105) *a*, Affinity of the enzyme for the template–primer, dT$_{12-18}$ · poly A. Each 20-μl reaction mixture was preincubated for 4 h at 0 °C and contained 2 μl BaEV RT, 10 mM sodium phosphate *p*H 8, 1% Triton X-100, 0.05% Tween 80, 130 mM NaCl, 5 mg ml^{-1} BSA, with or without 10 μg of IgG (purified through the DEAE agarose step) from eluates of CML patient HL 105 The enzyme activity was then assayed at 30 °C for 20 min in a 200-μl reaction mixture containing Tris–HCl *p*H7 4, H^3-dTTP 140 μM (3 6 Ci mmol^{-1}), 130 μM cold dATP, increasing amount of dT$_{12-18}$ · poly A (25–1,000 μg ml^{-1}), 50 mM KCl, 0.5 mM MnCl$_2$. *b*, Affinity of the enzyme for substrate, dTTP. Each reaction mixture was preincubated and the enzyme assayed as in *a* except that the concentration of template–primer was constant and saturating (200 μg ml^{-1}) and the concentration of dTTP was varied [10 μM H^3-dTTP (50 Ci mmol^{-1}) and unlabelled dTTP from 0–640 μM]. Left panels show the velocity of the reaction (pmol dTMP incorporated into TCA precipitates in 30 min) as a function of the amount of template-primer (*a*) or dTTP (*b*) in the reaction with (○) and without (●) 10 μg of CML antibody. Right panels show Lineweaver–Burk representation of the same data BaEV RT was used instead of FeLV RT to avoid complete RT neutralisation. In this case the IgG cross-reacted with BaEV RT

The biochemical and physical properties of the most purified fraction indicate that the inhibitor is IgG as: the specific activity is increased by procedures known to purify IgG; in some instances after purification of the IgG fraction, F(ab′)$_2$ fractions were prepared by pepsin digestion, isolated and purified by affinity chromatography using immobilised goat IgG specific for light chains. The specificity of RT neutralisation was retained in the fraction eluting as a F(ab′)$_2$ IgG fragment (Fig. 2*a*); protein bands were observed following SDS PAGE of affinity chromatography purified IgG which coincided with IgG heavy and light chains, and the inhibitory activity was stable to heating at 56 °C for 1 h and retained after dialysis.

The inhibition of RT activity is specific. Although comparable units of polymerase activity were used, positive samples showed inhibition of only certain mammalian type-C viral polymerases without inhibition of DNA polymerases from normal cells, from avian type-C viruses, or from mammalian type-B or type-D viruses. In most cases, the inhibitory activity further discriminated between RTs from various type-C mammalian viruses. The specificity was maintained with RT purified from one type of virus grown in several types of cells, for example, IgG from CML-BC comparably neutralised RT of FeLV grown in dog, cat or human cells and without neutralising RT from other viruses grown in the same cell (see legend to Fig. 1).

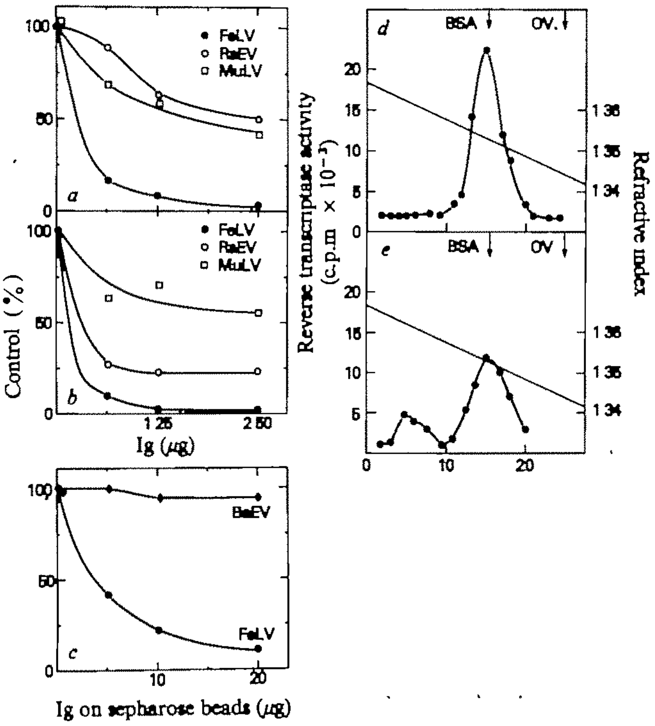

Fig. 4 Neutralisation, binding and precipitation assays for natural antibodies to mammalian type-C viral RT. Panels *a–c*, the IgG was the affinity chromatography purified IgG from blood leukocytes from CML blast crisis patient HL-70 *a*, Neutralisation of FeLV RT and cross-reaction with RT from rodent viruses Other polymerases were not inhibited (see Fig 2*e*). *b*, Indirect evidence for precipitation of RT from FeLV, murine leukaemia virus and rat type-C virus by IgG. Increasing amounts of IgG were preincubated with purified RT overnight at 0 °C in 40-μl reaction mixtures constituted as described in the legend to Fig 2. Then the samples were divided into two parts One half was assayed directly for inhibition of RT activity as shown in *a* The other half was centrifuged at 100,000 *g* for 10 min to pellet antigen–antibody complexes. The supernatant was collected and assayed for residual polymerase activity *c*, Binding of purified FeLV RT by immobilised IgG. Control normal human IgG and IgG from patient HL-70 were immobilised on cyanogen bromide activated Sepharose 4B beads. The IgG containing beads were tested for binding of purified polymerases by mixing the polymerase with the beads in a 0.05 M Tris–HCl, *p*H 7.4, containing 0.3 M NaCl, 2% Triton X-100, 10 mg ml^{-1} BSA, and 0 1% Tween 80. The mixture was incubated overnight at 0 °C, the supernatant collected after removing the beads by centrifugation, and the remaining polymerase activity in 50-μl aliquots of the supernatant was assayed as described in the legend to Fig. 1. No polymerase bound to the control normal human IgG (data not shown) which represents 100% activity. The results are % of control RT activity remaining in the supernatant *d*, Velocity sedimentation of purified SSV reverse transcriptase. Purified SSV RT was centrifuged at 40,000 r.p.m. for 16 h in a SW 50.1 rotor at 4 °C in a 5–20% linear sucrose gradient. Gradients were buffered with 25 mM Tris–HCl, *p*H 7.4, containing 10 mM sodium phosphate, 130 mM NaCl, 0 05% Tween 80 and 1% Triton X-100. Standards run simultaneously on parallel gradients were ^{125}I BSA (0 03 μg, specific activity, 75,000 c.p.m. μg^{-1}); ^{125}I-goat IgG (0.025 μg, specific activity 100,000 c.p m. μg^{-1}) *e*, Velocity sedimentation of SSV RT after incubation with natural antibody from a patient with CML-BC Method is as in *d* except that the SSV RT was incubated 4 h at 0 °C with 5 μg of purified IgG from patient HL-105 The amount of antibody used is the amount required for 70% neutralisation of SSV RT SSV RT was used instead of FeLV RT to avoid complete enzyme neutralisation

The purified IgG did not contain nonspecific inhibitors of RT. Inhibition of RT was not due to a protease which might degrade RT. The strongest evidence for this was the specificity of inhibition. In addition, the IgG fraction of the leukocyte eluates was tested for protease activity. Bovine serum albumin and purified RT from FeLV were labelled *in vitro* with ^{125}I and then incubated with either the crude leukocyte eluates, DEAE Agarose fractions or the affinity column fractions from several preparations. They were then assayed for proteases in the test IgG preparations by the release of acid soluble radioactivity or by the appearance of new radioactive peaks after velocity gradient centrifugation. As a positive control, the protein substrates were also incubated with protease K. Although the crude eluates contained protease activity, this activity was not found in the purified IgG preparations, emphasising the need to use purified IgG. Nucleases which might hydrolyse the template-primer or phosphatases which might degrade the deoxyribonucleoside triphosphate substrate were also not involved in the inhibition of RT activity. Enzyme kinetics with certain viral polymerases (known to be inhibited by a given affinity column purified leukocyte eluate) were studied with variable concentrations of template-primer at fixed and saturating concentrations of dTTP in the presence or absence of the purified IgG (Fig. 3*a*). In other experiments the concentration of dTTP was varied with a fixed and saturating concentration of primer-template with and without the IgG (Fig. 3*b*). In both experiments the V_{max} of the enzyme was substantially decreased in the presence of the inhibitor, but there was no change in K_m. This demonstrated that the inhibition was not competitive for primer-template or for substrate, indicating that inhibition was not due to contaminating nucleases or phosphatases. Furthermore, inhibition of RT by the IgG fraction was not dependent on the type of primer-template used for polymerase activity despite their variable susceptibility to nucleases. Comparable inhibitions were obtained with dT_{12-18} · poly A, poly d(A−T), dG_{12-18} · poly C and dG_{12-18} · poly C_m (data not shown). Finally, direct assays for nuclease activities were also negative. These were performed by measuring the release of radioactivity from labelled test nucleic acids in the presence of the purified IgG. Similarly, the concentrations of Mn^{2+} and Na^+ were varied to rule out the presence of a contaminating factor which might affect concentrations of cations optimal for RT activity. Again, no nonspecific effects were found. We conclude that the inhibitions directly involve RT.

Other assays for specific interaction of IgG with RT

When present in sufficient titre, specific antibodies against some viral structural proteins may directly precipitate the protein[35]. Compared with radioimmune precipitation assays, enzyme neutralisation assays combined with precipitation have the advantage of being based on the identifying characteristic of RT, that is, its enzymatic function. By incubating purified RT with the IgG overnight at 0 °C and then subjecting the sample to high speed centrifugation, RT activity present in the supernatant was quantitatively removed, suggesting that RT–IgG complexes had been precipitated (Fig. 4*b*). This precipitation was specific to only those RTs which were shown in separate experiments to be specifically inhibited by the IgG (Fig. 4*a*). Figure 4*a* and *b* also show that in addition to the complete neutralisation and precipitation of FeLV RT, RT from MuLV and rat endogenous

Table 3 Abrogation by GAH IgG of the anti-RT activity present in IgG fraction purified from peripheral blood leukocyte eluates obtained from a CML blast crisis patient

Reaction mixture*	RT activity† (pmol dTMP)	% Inhibition of RT‡
Control		
RT	7.0	0
RT+GAH IgG	6.0	0
RT+goat IgG	7.3	0
Experimental		
RT+eluate antibody (Ab)	3.1	54%
RT+(eluate Ab+GAH IgG)	5.6	16%
RT+(eluate Ab+goat IgG)	3.3	50%

* Experimental design includes assays of RT activity alone and after control preincubations with GAH IgG (50 μg) or with control goat IgG (50 μg) RT was also preincubated with 2.5 μg of IgG (here called eluate antibody) purified from eluate of blood leukocytes from patient HL-62 with CML (BC) either alone or in the presence of GAH-IgG or with control goat IgG. RT was purified from FeLV.

† RT activity expressed in pmol dTMP incorporated into TCA precipitates in 30 min (total c.p.m. = 30,000). Assay conditions are given in the legend to Fig. 1.

‡ % inhibition of RT were calculated from the mean value of controls.

type-C virus (RaEV) were partly affected by IgG from patient HL-70. Other viral and cellular polymerases were not affected (Fig. 1e). This specificity pattern is similar to the usual cross-reactivity of natural antibodies to FeLV RT present in sera from some FeLV-infected cats[22].

The natural antibody binds specifically to type-C viral RT. Purified IgG from patient HL-70, which specifically inhibited RT from FeLV and to a lesser extent RT from rodent leukaemia viruses (Figs 1e, 4a), was tested for binding to RT as follows. The IgG was immobilised on cyanogen bromide-activated Sepharose 4B beads. The beads were then incubated with various DNA polymerases, the supernatant collected after removal of the beads and the polymerase activity remaining in the supernatant determined (Fig. 4c). FeLV RT activity was specifically removed by incubation with this immobilised IgG but not with immobilised control human IgG (Fig. 4c).

We also assayed the binding of antibodies to RT by assays dependent on the physical properties of RT activity. For this purpose, the velocity sedimentation rates in sucrose density gradients were determined for RT compared to RT preincubated with purified IgG. Concentrations of antibody (patient HL-105) were used which only partially neutralised the test RT so that some enzyme activity remained to follow the position of the RT–IgG complex in the gradient. Figure 4d shows the activity of the enzyme alone and Fig. 4e the residual activity measured through the gradient in the presence of IgG. A clear shift was observed in the enzyme activity peak to a more rapidly sedimenting peak.

The RT inhibitory activity present in the IgG can be removed by GAH-IgG. If all the inhibitory activity for viral RT were due to a specific IgG antibody reaction, the inhibitory effect of the IgG would be lessened by pretreating it with an antibody to human IgG, which was the case (Table 3). Purified FeLV RT was inhibited 55% with 2.5 μg of purified antibody fraction from leukocyte eluates obtained from CML-BC patient HL-62. When the CML antibody fraction was pretreated with goat anti-human IgG, the inhibitory effect was reduced by 75%. FeLV RT was not inhibited by GAH IgG or goat IgG.

Conclusions

The results reported here show that blood and bone marrow leukocytes carry surface proteins that can be eluted into serum free medium. Among these proteins were IgG molecules reactive with specific RTs from certain mammalian type-C oncornaviruses. Among the viral RTs tested, RT from FeLV and in some instances RT from SSV, were the main DNA polymerases neutralised by IgG from blood or bone marrow cells derived from patients with myeloblastic leukaemias. The results exclude a specific interaction of the IgG with a cell protein co-purifying with viral RT as the specificity against a given RT was maintained with viruses grown in different kinds of cells from diverse species (for example, specificity of CML-BC IgG for FeLV RT with FeLV grown in either cat lymphoblasts, human lymphoblasts, or dog fibroblasts and of some AML IgG for SSV RT with SSV grown in dog thymus cells and human cells). Specificity was also maintained when different viruses were grown in the same cell (for example, a specificity of CML-BC IgG for FeLV RT when FeLV, MPMV and BaEV were grown in NC37 human lymphoblasts). Moreover, anti-RT IgG was not specifically adsorbed by uninfected cells used to grow the virus (data not shown). However, the genesis of these antibodies is unclear. It is possible that the IgG was directed against an RT which was present earlier in leukaemic and/or other cells and is now nonspecifically bound to Fc receptors on some blood cells[36] present in the leukaemic blood cell population, but this is unlikely in view of other data[20,21]. It is also possible that the IgG is directed against a cell protein, mimicking mammalian type-C viral RT. This possibility cannot be excluded until the antigen is identified and chemically characterised. However, in view of the specificities shown, we think this interpretation is unlikely and our working hypothesis is that the IgG is directed against RT present on the cell membrane either as a mature protein or in the form of a polyprotein precursor as shown with some other viral proteins[37] and recently also with RT precursors[38]. In the latter study, Witte and Baltimore reported finding RT precursors on membranes of cells infected by temperature-sensitive mutants of MuLV blocked at late stages of assembly. They did not detect enzymatically active RT except when virions were formed and released. Therefore, active RT may only be made inside released, newly made virions[38]. However, results of Wong and Kang clearly show enzymatically active viral RT in ribonucleoprotein complexes (without viral structure) present intracellularly in reticuloendotheliosis virus-transformed chicken bone marrow cells[39]. Intracisternal as well as intracytoplasmic A-particles have been repeatedly shown to contain catalytically active RT. Our experience[3,9–11] and that of others[13,40] indicates that a catalytically active RT-like DNA polymerase can sometimes be identified in some fresh human leukaemic cells and also in ribonucleoprotein complexes without demonstrable virions. In some cases of AML this polymerase immunologically cross-reacted with RT from viruses of the SSV-GaLV group[3,9–13]. These studies did not comprehensively include assays for: catalytically inactive RT, active or inactive RT in cell membranes, and FeLV or rodent virus-related RT. These studies are clearly needed in view of the recent data[38] and data reported here.

IgG may be associated with a specific type of cell, but this is not yet known because peripheral blood cells and bone marrow cells are heterogeneous even in the leukaemias. However, the absence of IgG with anti-RT activity from normal blood lymphocytes (purified by nylon column chromatography), the low or negative results with lymphoid leukaemia, combined with the positive results with some whole blood from normal donors and from patients with myeloid leukaemias, suggest that the antibodies are chiefly associated with non-lymphocytic cells.

There have been surprisingly few studies of antibodies against RT in animal models. One study in AKR mice indicates that such antibodies may be isolated from kidney eluates[41]. Serum of some animals naturally infected by retroviruses have antibodies to RT. This has recently been found in some cats infected with FeLV[22], some gibbons infected with GaLV[23] and some cows infected with bovine leukaemia virus[24] It would be of interest to determine if anti-RT IgG can be found on the surface of leukaemic blood cells of animals, particularly from non-virus producers, as a model for the results reported here.

These results provide additional evidence for the association of type-C viral information with humans, but we do not regard them as demonstrating the presence in humans of any animal virus used here These viruses were used to supply probes to detect antibodies which may have been directed against proteins derived from related information. For example, a number of other tests for FeLV components in humans carried out in our laboratory were negative, including tests for FeLV p30-related antigens in whole cell extracts of several of the samples used here and for anti-p30 activity in the leukocyte eluate IgG with anti-RT activity. Previous data obtained with probes derived from the available type-C viruses indicate that no human leukaemic blood cell sample tested contained complete provirus (of any of these viruses) in the majority of the cells[42–46] Six of the CML-BC samples shown here to contain anti-RT activity against FeLV were also tested by conventional molecular hybridisation techniques and were negative for FeLV proviral sequences, providing strong evidence against active replication of FeLV or a closely related virus in these cells. On the other hand, some non-viraemic leukaemic cats do not have detectable serum antibodies to viral proteins and proviral sequences may be difficult to demonstrate[47], despite evidence for FeLV infection as suggested by the presence of feline oncornavirus membrane antigen in the tumour cells. Also, Spiegelman reported[40] small amounts of nucleic acid sequences in all human leukaemic DNA tested which were not found in DNA from normal cells, suggesting that leukaemic cells contain acquired viral sequences and some studies indicate that the extra sequences in some cases are partly homologous to sequences of certain mammalian type-C viruses. This might be explained by the presence of incomplete provirus, by insufficient homology of the probes or by a presence of proviral sequences in a limited number of cells as described elsewhere[34]. Therefore, it seems possible that the positive findings reported here could indicate an immunological response against the test virus used. This seems especially the case with FeLV where there is both obvious contact by humans with virus-shedding cats and known ability of the virus to infect human cells[48,49]. The presence of antibody with relatively high activity and specificity to FeLV RT in CML-BC and the absence to date of IgG with similar anti-RT specificity in CML chronic phase, in CML in remission and in randomly selected normal blood samples might help in the detection of early blast transformation in this disease. Similarly, further distinction between IgG from AML and IgG from normal blood leukocytes characterised in the former case by a preferred reactivity against RT from SSV and in the latter case RT from $\mathrm{GaLV}_{\mathrm{SF}}$, may be useful in following patients in remission and in preleukaemic states.

We thank Drs M. Essex, R. Gallagher, D. Bolognesi, R. Metzgar, J. Schlom, R. Knight, M. Robert-Guroff, M. Sarngadharan, S. Aaronson, D. Gillespie, P. Sarin, E. Fleissner, H. Snyder and W. Hardy for discussions, Drs G. Bekesi and K. McCredie for sending us leukaemic cells and clinical information and Marianne McGee, Barbara Fleudelys and George Coy for technical assistance.

Nucleotide sequence of bacteriophage G4 DNA

G. N. Godson*, B. G. Barrell, R. Staden & J. C. Fiddes†

MRC Laboratory of Molecular Biology, Hills Road, Cambridge, UK

The 5,577 nucleotide long sequence of bacteriophage G4 DNA has been determined using the 'plus and minus' and chain termination methods of DNA sequencing. This sequence has been compared with that of the closely related bacteriophage ΦX174 (refs 1, 55). In the coding regions there is an average of 33.1% nucleotide sequence differences between the two genomes, but the distribution of these changes is not random and the sequence of some genes is more conserved than others. There is less sequence similarity between the untranslated intergenic regions of G4 and ΦX174, but despite this the sequences of the J/F, F/G and H/A untranslated spaces in both genomes have similar sized hairpin loops, which may be related to their function.

BACTERIOPHAGE G4 is a small isometric ΦX-like phage that was isolated in 1974 (ref. 2). Like ΦX174, it contains single-stranded circular DNA and the two phage genomes code for the same series of eleven proteins[2,3]. However, G4 and ΦX174 do not recombine or complement efficiently[56] and electron microscopy of ΦX174/G4 DNA heteroduplex molecules indicates that there is an overall 39% base sequence mismatch between the two DNA molecules[2]. This base sequence difference has been confirmed by the lack of similarity of the fragments obtained by restriction endonuclease digestion of ΦX174 and G4 DNA (refs 4, 5, 57). The physical maps of the two phages have, however, been aligned by detecting hybridisation between the two sets of restriction enzyme fragments[6,56].

The major physiological difference between ΦX174 and G4 is in the mechanism of DNA replication. Initiation and synthesis of the complementary DNA strand in ΦX174 requires the eight proteins dnaB, dnaC/D, dnaG, i, n, polIII holoenzyme and DNA binding protein[7,8] while in G4 it requires only three proteins, dnaG, polIII holoenzyme and DNA binding protein[9]. Also, initiation of the G4 complementary DNA strand occurs at a single unique site both *in vitro*[10] and *in vivo*[11,12], but in ΦX174 initiation of the complementary DNA strand occurs at multiple randomly located sites[13,14].

Recently, the complete nucleotide sequence of ΦX174 has been established[1,55]. We report here the determination of the complete G4 nucleotide sequence (see Fig. 1). The G4 sequence was derived using the enzymatic priming 'plus and minus'[15] and chain termination[16] methods of DNA sequencing and extensive use was made of a computer to store and build up the G4 sequence and compare it with ΦX174. More detailed accounts of certain regions of the G4 genome and of the sequence determination are presented elsewhere[3,17,58] and a description of the computer programs used has been published[18,19].

Structure of the G4 genome

The G4 genome is 5,577 nucleotides long, 191 nucleotides longer than the ΦX174 genome[55] and, like ΦX174, it codes for 11 genes. Four of these genes specify virion structural proteins (genes *F*, *G*, *H*, and *J*), five genes specify proteins involved in viral DNA replication and phage assembly (genes *A*, *A**, *B*, *C* and *D*), one gene specifies a lysis protein (gene *E*) and the function of the new overlapping gene *K* protein[3] is not known. On SDS polyacrylamide gels (PAGE) of UV-irradiated infected cells, nine of these gene products can be identified as protein bands[2,3]. A genetic map of G4 has not been established, but a comparison of the G4 and ΦX174 nucleotide sequences indicates that the gene order in G4 is the same as in ΦX174.

Table 1 Conservation of nucleotide and amino acid sequences in the coding regions of G4 and ΦX174

Gene	Codons in G4 / Codons in ΦX174	% Amino acid changes	% Nucleotide changes	% Codon changes not changing the amino acid*	% Codons with U in the third position: G4	% Codons with U in the third position: ΦX174

The changes have been calculated from the ΦX174 sequence[55] and the G4 sequence when they have been aligned for maximum homology, and take into account deletions and insertions with respect to ΦX174. In all cases the initiation codon has been included but not the termination codon. The amino acid and nucleotide mismatches are calculated by aligning the coding regions from the ATG start and comparing the sequence, counting each deleted or inserted nucleotide as a mismatch. (For the calculations that do not include the deleted or inserted nucleotides see ref 60.)

* Nucleotide changes in the third position of the codons and other conservative codon changes that do not change the amino acid. Results are expressed as: (the no. of conservative codon changes × 100)/total no. of codons.

† These genes have insertions and/or deletions with respect to ΦX174

‡ Overlapping gene regions: A(B), region of gene *A* which overlaps gene *B* (A phase); A(K), region of gene *A* which overlaps gene *K* (A phase); C(K), region of gene *C* which overlaps gene *K* (C phase); D(E), region of gene *D* which overlaps gene *E* (D phase).

In the coding regions of G4 and ΦX174 DNA, there are enough similarities in nucleotide sequence to align the two genomes and make a gene-by-gene comparison. Some of the G4 genes are slightly larger than their ΦX174 counterparts, but only in the gene *A*, *H* and *J* coding regions are there any gross changes in size (see Table 1). The larger size of the G4 genome is mainly due to an insertion of 141 nucleotides in the G4 gene *A* coding region compared with ΦX174, increased sizes of the G4 untranslated intergenic spaces (G4 has 282 or 5.0% untranslated nucleotides and ΦX174 has 217 or 4.0% untranslated nucleotides) and duplication at the 3′ end of the G4 gene *D* which introduces a 32 nucleotide long untranslated region between genes *E* and *J* that is not present in ΦX174. Also there are small insertions and deletions in G4 relative to ΦX174 elsewhere throughout the genome. A comparison of the overall structure of the G4 and ΦX174 genomes is shown in Fig. 2.

Coding regions of the G4 genome

The reading frame and starts of the G4 gene *J* and *K* coding regions[3] and gene *B*, *C*, *D*, *F*, *G* and *H* coding regions[59] were established by sequencing the first 15 to 30 N-terminal amino acids of ^{14}C-labelled G4 proteins. These proteins were isolated from SDS PAGE of UV-irradiated infected cell lysates and analysed by a radioactive microsequence method[20,21].

The phasing defined by the N-terminal amino acid sequences agrees with the phasing determined for the same genes in ΦX174 (ref. 1) and the N-terminal amino acid sequence of the G4 gene *C* protein clearly defines the start of the gene *C* coding region as overlapping with the termination codon of gene *A* (A-T-G-A) which was uncertain in ΦX174. The reading frames and initiation codons of the G4 *A* and *E* gene coding regions were established by analogy with ΦX174. The A* protein is a translational restart of the A reading frame[22] and from consideration of the size of the G4 A* protein the start of the A* coding region is most probably at nucleotide 698 (Fig. 1) which is an A-T-G codon preceded by a sequence complementary with the 3′ end of 16S rRNA (see Table 3). A correction to the ΦX174 sequence in this region[55] agrees with this prediction.

In the coding regions, the average base sequence difference between G4 and ΦX174 is 33.1%. The distribution of these changes, however, is not random and varies from gene to gene. For instance, in the non-overlapping genes 51.7% of the nucleotides in G4 gene *G* are different from their ΦX174 counterparts, while in gene *H*, 35.7% of the nucleotides are different. In the regions of the genome containing overlapping genes, the nucleotide differences are slightly lower (see Table 1).

The amino acid differences between the G4 and ΦX174 proteins again differ with the gene. Except in the case of gene *G* protein, in which 60.1% of the G4 amino acids are different from their ΦX174 equivalent, the differences in amino acids between the G4 and ΦX174 virion structural proteins (F, G, H and J) is no greater than in the non-virion structural proteins A,

Fig. 1 Nucleotide sequence of bacteriophage G4 wild-type DNA. The sequence of the circular DNA molecule is written starting after the termination codon for the *H* gene and is numbered accordingly. The letters in the left hand margin indicate the protein whose amino acid sequence is shown in the corresponding line. Restriction enzyme recognition sites are underlined. The single letter code used for the enzymes is as follows: A, *AluI*; F, *HinfI*; H, *HhaI*; K, *KpnI*; M, *MboII*; P, *PstI*; R, *HindII*; RI, *EcoRI*; T, *TaqI*; Y, *HpaII*; Z, *HaeIII*. The G4 promoters and origins of DNA replication are marked accordingly. Nucleotides 87, 91, 1123, 2,780–2,790, 2952, and 4,096–4,098, are tentative. The amino acids are those predicted from the nucleotide sequence.

B, C, D, E and K which are presumed to have an enzymatic function in synthesis and assembly of the virus. The am acid differences between the poteins o te tw pha on in Tabl 1e *D* is the most highly conserved protein between the two phages, with only 17.8% o h msnge, uths eprtly de to the presence of the overlapping *E* gene within the gene *D* coding region (see below). The amino acid differences do not always correlate with the nucleotide differences of the coding region. This is because in some genes a high percentage of nucleotide differences are in the third degenerate position of the codon which conserves the amino acid sequence (compare gene *D* with gene *G* in Table 1).

Overlapping genes

Two overlapping gene systems have been identified in ΦX174 in which the nucleotide sequence is read in two different phases. These are gene *E* which is entirely coded within the gene *D* coding region[23] and gene *B* which is entirely coded within the gene *A* coding region[24,25]. Both of these overlapping gene systems are present in G4. The G4 gene *B* coding region has been identified by sequencing the 20 N-terminal amino acids of the G4 protein[59] and it is contained within G4 gene *A* coding region, exactly as in ΦX174. Gene *E* protein has not yet been identified on SDS PAGE either in ΦX174 or G4 and the location of the gene *E* coding region in the G4 genome has been deduced from similarities with the ΦX174 sequence (that is, the conservation of a gene *E* ribosome binding site sequence, the A-T-G initiation codon and the characteristic hydrophobic N-terminal amino acids). The G4 *E* gene coding region starts in the same position as the ΦX174 *E* gene, but it is five codons longer and, unlike ΦX174, the G4 *E* gene coding region extends beyond the end of the *D* gene (see Fig. 2). A third overlapping gene system has been identified in G4 (ref. 3). This is gene *K* which is coded as a second phase of genes *A* and *C*, crossing the junction of those two coding regions (see Fig. 2). This overlapping gene system was identified by isolating the G4 K protein and determining part of its amino acid sequence. G4 gene *K* is of particular interest because five nucleotides of its coding region are read as a third phase of pre-existing overlapping genes (see Figs 1 and 2).

The nucleotide differences between the overlapping gene regions of the G4 and ΦX174 genomes are shown in Table 1. The frequency of changed nucleotides in the G4 gene *B*, *K* and *E* coding regions compared with the same regions in ΦX174 are 23.9%, 23.8% and 23.3%, respectively. This is approximately 10–20% below the frequencies for the non-overlapping genes. However, in the three overlapping genes, fewer of the nucleotide changes are third position or conservative codon changes and this results in the gene *B*, *K* and *E* proteins having a higher than average amino acid difference between the two phages. It would appear, therefore, that there is considerable selective pressure to preserve the gene *A*, *C* and *D* amino acid sequence.

This agrees with the suggestion made previously[23] that gene *E* in ΦX174 arose at a later stage of evolution than the *D* gene and was a result of the phage utilising the high incidence of D phase codons ending in T to generate a second phase protein which was hydrophobic, as codons with T in the second position specify hydrophobic amino acids. It may be inconsistent, however, with the suggestion[24] that the present day overlapping *A* and *B* genes are a result of an evolutionary readthrough of a separate *A* gene into a pre-existing *B* gene coding region.

The most noticeable feature of the gene *E* and *K* proteins is their strongly hydrophobic N terminus. Both G4 gene *E* and *K* proteins have 10 leucine residues in the first 25 N-terminal amino acids and these are distributed in two blocks in a manner similar to certain secretory precursor proteins[3,26]. This suggests that the most important feature to preserve in these proteins is their hydrophobic N terminus and the amino acid sequence of the rest of the molecule is more free to drift in evolution.

Thus in the overlapping coding regions of G4 and ΦX174, the frequency of nucleotide change is only slightly lower than in the non-overlapping coding regions and the increased number of amino acid changes in the overlapping gene proteins appears to be accommodated by the lack of stringency in the amino acid sequence. Use of the DNA sequence in two concurrent reading frames need not, therefore, be a significant barrier to evolutionary change

Codon use

G4 DNA does not have the same high T content as ΦX174 DNA and its base composition as obtained from the nucleotide sequence is A, 27.17%, C, 25.93%, G, 19.80%, and T, 27.11%. This compares with the ΦX174 base composition of A, 23.95%, C, 21.48%, G, 23.30% and T, 31.27% (ref. 55). The high frequency of codons with T in the third position that was noted in ΦX174 (ref. 27) is not so marked in G4. Overall, 33 8% of the G4 codons have T in the third position compared with 43.0% in ΦX174. A gene-by-gene analysis of the number of codons with third position T is shown in Table 1. It is noticeable that in the overlapping gene regions of the genome, the percentage of codons with T in the third position is high and almost the same in both G4 and ΦX174, but in the non-overlapping gene regions which code for the structural virion proteins, although the incidence of third position T is still high in ΦX174, it is much lower in G4.

The spectrum of codon use in G4 is similar to that in ΦX174. This is shown in Table 2 and is compared with the codon use in MS2, which is the only prokaryotic virus for which extensive information is available[28]. Some codons are rarely used in G4. For example, out of a total of 123 Arg codons, only 4 and 6 are A-G-G and A-G-A respectively, and out of 139 Gly codons, only five are G-G-G. The figures are similar in ΦX174. In general, codons ending in G-G and G-A are rare in both G4 and ΦX174. These rare codons may have a modulating role in translation if their corresponding tRNA is also rare, as suggested by Fiers *et al*[28] The use of codons by these three prokaryotic viruses is considerably different from the use of codons by the eukaryotic virus SV40 (refs 29, 30).

Most of the G4 and ΦX174 genes have the same termination codons, except for genes *F* and *G*, which use T-A-A in G4 and T-G-A in ΦX174. The A-T-G-A overlapping termination codon of gene *A* and initiation codon of gene *C* is present in both genomes, but the two other overlapping ΦX174 termination and initiation codons (genes *C*/*D* and *D*/*J*) are not present in G4.

Untranslated regions

There are untranslated sequences between most of the G4 coding regions and two of these (between G4 genes *E* and *J* and genes *C* and *D*) are not present in ΦX174. This is shown in Fig. 2. One of the new G4 intergenic spaces is a result of a duplication of the 3′ end of the overlapping G4 gene *D* and *E* coding regions which introduces a 32–nucleotide untranslated sequence between the *E* and *J* genes[55]. The other new intergenic space has been introduced by changes in the end of the G4 gene *C* coding region relative to ΦX174, which has resulted in a loss of two gene *C* codons and an insertion of one untranslated A nucleotide between the G4 *C* and *D* genes. In G4 the sequence T-G-A-A-A-T-G has replaced the overlapping gene *C* and *D* termination and initiation codons (T-G-A-T-G) present in ΦX174 (Fig. 1).

The sequences of the H/A and J/F intergenic regions are about 50% conserved between the G4 and ΦX174 genomes when they are aligned for maximum homology. The large F/G and the small G/H intergenic regions, however, show little sequence homology between the two bacteriophages. Despite the sequence differences, the three large intergenic spaces in both G4 and ΦX174 (J/F, F/G and A/H) can form hairpin loops which are in the same relative position in the sequence and have similar size and geometry. This is illustrated in Fig. 4 which shows the untranslated sequences between G4 and ΦX174 genes *H* and *A*. The similarity of the 3′ end of the sequence is a special case because of the presence of a ribosome binding site, a promoter and an mRNA termination site. The conservation of the hairpin loops in the J/F and H/A untranslated regions is believed to be related to the transcriptional termination sites observed in these regions in ΦX174 (see below).

The G4 untranslated region between genes *G* and *F* contain three hairpin loops[17] compared with two in ΦX174 (ref. 31) and one of these in G4 is associated with the origin of G4 complementary DNA strand synthesis. The function of the other hairpin loops in this region in G4 and ΦX174 is not known.

G4 promoters and mRNA termination sites

There is little information on transcription and translation in G4. Three G4 RNA polymerase binding sites have been identified by filter binding experiments[32] and these appear to correspond with the three RNA polymerase binding sites observed in analogous experiments in ΦX174 (ref. 33). Two of the ΦX174 RNA polymerase binding sites have been shown by mRNA studies[34–37] to be the gene *A* and gene *D* promoters, but

Fig. 2 Aligned physical genetic maps of bacteriophage G4 and ΦX174. The G4 and ΦX174 genetic maps are drawn to scale from the G4 (Fig. 1) and ΦX174 (refs 1, 55) nucleotide sequences The lengths of the untranslated regions are shown above the intergenic spaces The locations of the three promoters (P_A, P_B and P_D) and the origins of viral DNA strand synthesis (O_V) and complementary DNA strand synthesis (O_C) are described in the text. The position of the nucleotides inserted and deleted in the G4 coding regions relative to ΦX174 have been deduced from an alignment of the complete G4 and ΦX174 nucleotide sequences.

the third binding site is in gene *G* where no mRNA is known to start.

The third ΦX174 promoter—that preceding the *B* gene—has been identified in the ΦX174 nucleotide sequence (ref. 1 and J. Sims and D. Dressler, personal communication). The similarity of the G4 sequence and ΦX174 sequence in the regions of the ΦX174 promoters suggests that the three G4 promoters are in the same location as in ΦX174. The sequences of the ΦX174 gene *A*, *B* and *D* promoters with the analogous G4 sequences are shown in Fig. 3. Note that all six sequences preserve the common feature of having a sequence similar to T-A-T-Pu-A-T-Pu centred about eight nucleotides from the mRNA initiation point[38,39] and a sequence similar to T-G-T-T-G-A-C-A-A-T-T-T centred about 35 nucleotides from the mRNA initiation point (refs 40, 41 and J. Majors, unpublished). The 5′ end of the major G4 mRNA species can therefore be predicted as A-U-C-A-A (gene *A*), G-U-A-A-C (gene *D*) and A-U-C-G-C-A (gene *B*).

16S rRNA 3′ end	$_{\text{HO}}$A-U-U-C-C-U-C-C-A-C-U-A-G

The main mRNA termination site in ΦX174 has been identified at the 3′ end of a T-T-T-T-T-T-A sequence located at the base of the hairpin loop in the untranslated region between the *H* and *A* genes (J. Drouin, unpublished) (Fig. 4). Similar T_6A sequences have been found at the 3′ end of RNA transcripts in phage λ (refs 42, 43) and in bacteriophage fd (ref. 44), and in both these cases it has been suggested that the hairpin loop preceding the T_6A sequence is an important signal for transcriptional termination. In G4 there is a T-T-T-T-C sequence instead of a T-T-T-T-T-T-A at the base of the hairpin loop in the H/A untranslated region (Fig. 4) and from analogy this is most probably the major G4 mRNA termination site.

A minor ΦX174 mRNA termination site has been identified to the 3′ side of the hairpin loop in the J/F untranslated region (J Drouin, unpublished). This hairpin loop is also conserved in G4 but with no sequence homology, and it is not known whether there is a transcriptional termination site in this position in G4

G4 Ribosome binding sites and possible new overlapping proteins

Table 3 shows the sequences preceding the A-T-G initiation codons of known G4 coding regions. The nucleotides complementary to the 3′ end of 16S RNA which are characteristic of ribosome binding sites[45] are indicated. The five G4 ribosome binding sites that occur in the untranslated intergenic spaces (those for genes *A*, *J*, *F*, *G* and *H*) have different sequences from the same sites in ΦX174 whereas the G4 ribosome binding sites that occur in coding regions of the preceding gene (those for genes *A**, *B*, *K*, *C*, *D* and *E*) are almost identical to their ΦX174 counterpart.

In G4 there appear to be other sites which could code for a protein. There are 13 sites in the genome which have complementarity with the 3′ end of 16S ribosomal RNA and are located within 14 nucleotides of an A-T-G initiation codon and followed by an open phase of at least 20 codons (Table 4). Only two of the G4 potential initiation sites are present in ΦX174 (which has others that are not represented in G4 (ref. 46)) and would specify the same length protein. These are the G4 A2a (and A2b in the same phase) and F2 potential proteins (Table 4). It is not known whether any of these sites are used to synthesise a so far undetected protein *in vivo*, but one new G4 overlapping gene, ***K***, was predicted in this manner from the nucleotide sequence and the protein was subsequently found[3].

Origin of G4 viral DNA strand synthesis

G4 has a unique origin of synthesis of its viral and complementary DNA strands which are separated and on almost opposite sides of the genome (Fig. 2). The *in vivo* origin of the G4 viral DNA strand has been located by pulse label experiments[47,11] and by electron microscope mapping of the 5′ end of the tail of late rolling circle replicative intermediates[48]. It is in the *Haemophilus aegyptius* restriction endonuclease fragment *Hae*III2b near the junction of the *H. influenzae* restriction endonuclease fragment *Hin*dIIA and D. When the G4 and ΦX174 sequences are compared across this region[17], there are 30 nucleotides (500–529 in Fig. 1) which are identical in both genomes and within this sequence the ΦX174 cistron A protein is known to cleave ΦX174 double-stranded DNA and initiate viral DNA strand synthesis[49]. This cleavage is between the G and A nucleotides which correspond to G4 nucleotides 506 and 507 in Fig. 1. On the 5′ and 3′ sides of the conserved sequence there are considerable differences between the G4 and ΦX174 sequences but in both cases the cistron A cleavage site is in an A-T-rich sequence (501–523 in G4) flanked by G-C-rich sequences (490–500 and 524–541 in G4). The conservation in G4 of this feature and the sequences around the ΦX174 cistron A protein cleavage site strongly suggest that the G4 origin of viral DNA strand synthesis is in the same place as in ΦX174, between G4 nucleotides 506 and 507.

Fig. 3 Promoter sequences in G4 and ΦX174 The ΦX174 promoter sequences are taken from Sanger *et al.*[1] and the ΦX174 nucleotide numbering is taken from the corrected ΦX174 DNA sequence[55]. The boxed regions indicate homology with T-A-T-Pu-A-T-Pu[38,39] and T-G-T-T-G-A-C-A-A-T-T-T (refs 40, 41 and J Majors, unpublished) The locations of the ΦX174 mRNA starts are shown with arrows.

Origin of G4 complementary DNA strand synthesis

G4 has single unique origin of synthesis of its complementary DNA strand, both *in vitro*[9] and *in vivo* (refs 11, 12). Initiation *in vitro* involves synthesis of an RNA primer molecule[10] the sequence of which has now been determined[50]. This 28-nucleotide RNA sequence corresponds to a G4 DNA sequence in the untranslated region between genes *F* and *G* (ref. 17 and J. Sims and D. Dressler, personal communication) and the 5′ end of the primer RNA is at nucleotide 3,997 in Fig. 1. The DNA corresponding to the RNA primer sequence can be drawn in the form of a stable hairpin loop (positions 3,972–3,992 in Fig. 1). Two other hairpin loops are formed in the G4 region between genes *F* and *G* and these appear to be analogous to the loops observed in this region in ΦX174 (ref. 31). ΦX174 does not have a loop corresponding to the G4 RNA primer and there is no evidence for a preferred initiation site for complementary DNA strand synthesis in ΦX174.

It is interesting to note that the sequence of 42 nucleotides on the 3′ side of the primer RNA loop in G4 (before the 5′ start of

Fig. 4 Untranslated region between genes *H* and *A* The ΦX174 nucleotide sequence is from ref. 1 and the identification of the *A* promoter sequence, the ribosome binding site and mRNA termination sites are discussed in that paper. The G4 promoter ribosome binding sites are deduced from analogy with the ΦX174 nucleotide sequences (see text)

* Sites are named according to which gene they occur in and the order in which they occur in that gene. Sites labelled a, b, etc. are in the same reading frame.

† Numbers refer to the A of the A-T-G initiation codon.

‡ Only those sequences that have at least three consecutive nucleotides complementary to the boxed sequence at the 3′ end of the 16S rRNA are included. Other restrictions are that these complementary sequences must not be closer than two nucleotides and not further than 14 nucleotides from the A-T-G, and must have at least two potential G/C base pairs with the 16S sequence shown boxed. Possible extra initiation sites in the same reading frame as known genes are not included nor are sites containing G-T-G initiation codons.

§ Length of the polypeptide that could be produced starting at the A-T-G initiation codon. Only those sites that could specify a polypeptide of greater than 20 amino acids have been considered.

the primer RNA) has 26 nucleotides in common with phage λ origin of DNA synthesis[51]. This common sequence, together with the hairpin loops that are present in both organisms, may represent the dnaG protein (primase) binding site. The equivalent sequence in ΦX174 has only 11 nucleotides in common with G4.

Location of the *Eco*RI and *Eco*B restriction sites in G4

G4 grows only on *Escherichia coli* C strains and is restricted by K12 and B strains and by strains carrying the plasmid RY (ref. 52). The single *Eco*RI restriction enzyme cleavage site (G-A-A-T-T-C) is at position 3,596 (Fig. 1) and the single *Eco*B restriction site (T-G-A-8N-T-G-C-T)[53,54] is located between positions 4,523 and 4,537 on the complementary strand. Neither of these sites is present in ΦX174.

Evolution of G4 and ΦX174

The comparative G4 and ΦX174 nucleotide sequence presents an opportunity to analyse the mechanism of evolution simultaneously on both the nucleotide and amino acid levels. It is clear that G4 and ΦX174 are closely related and have the same overall genome structure and organisation of gene function. The main nucleotide differences between the two genomes are most probably explained by single step mutational nucleotide changes and the increased size of the G4 genome (+3.5%) could probably have taken place by duplications of the sort that are still evident at the end of the G4 gene *D* (nucleotides 2,420–2,434 containing the gene *J* ribosome binding site and initiation codon and the gene *D* termination codon are repeated at positions 2,463–2,477). However, any evolutionary description will have to take into account the following observations: (1) the intergenic untranslated regions of G4 and ΦX174 are different in size and sometimes quite different in nucleotide sequence; (2) both insertions and deletions in one genome relative to the other occur in single gene coding regions (genes *A*, *G* and *H*) and occur in units of triplets so that the amino acid phasing is not changed; (3) alternative serine codons (A-G-C to T-C-T) are used in one phage relative to the other in regions of highly conserved amino acids (for example, at positions 1,186 and 1,304 in gene *A*). An A-G-C to T-C-T change cannot take place in single steps without changing the amino acid. These changes may have taken place by the known recombinational mechanisms acting on the pool of replicating viral DNA or even within a single genome (that is, intramolecular recombination) rather than deletions and insertions on codon unit lengths of DNA.

The authors thank Dr F. Sanger for advice, encouragement and for a gift of chain termination compounds and the use of the chain termination method of DNA sequencing before publication. We also thank Drs J. E. Walker and D. C. Shaw for amino acid information on the G4 proteins. G.N.G. was supported by USPHS grant no. CA-06519 and American Chemical Society grant no. SG-86.

Positions and identifications for galactic X-ray sources 2A1822−371 and 2S1254−690

PRECISE positions and optical identifications for the galactic X-ray sources 2A1822−371 (4U1822−37) and 2S1254−690 (4U1254−69), are presented here using the scanning modulation collimator (MC) on HEAO 1 (ref. 1). Briefly, the HEAO 1 MC instrument contains two independent four-grid collimator systems, one having planes of maximum transmission with 30 arc s. FWHM, and the other having 120 arc s FWHM, the overall field of view of each being limited to 4°×4° FWHM. The planes of transmission of the modulation collimators are inclined at ±10° to the scan direction, so that the lines of position from each have an included angle of 20°. Data are folded and binned around the catalogued positions[2–4] of X-ray sources in the manner described by Gursky *et al.*[1].

2A1822−371($l^{\mathrm{II}}=356°$, $b^{\mathrm{II}}=-11°$): data were accumulated in scans across 2A1822−371 for a total of 59 orbits, from 25 to 29 September 1977 UT, when the source was within ±2° of the HEAO 1 scan circle. The source was detected at 14.7σ above background in the 30 arc s collimator (MC1) and at 13.5σ in the 2 arc min collimator system (MC2). The strength of the source was measured as 6 UFU (1 Uhuru flux unit $=1.7\times10^{-11}$ erg cm^{-2} s^{-1}, 2–6 keV). This is to be compared with maximum catalogued intensities of about 25 UFU[2,3,6] and a minimum of 6 UFU[3]. The present observations were thus taken when the source was weak. Of the multiple possible positions obtained by the instrument, only one falls within either the 2A or 4U error boxes for the X-ray source, this one MC position (of area 0.6 arc min^2) being entirely within the 2A box (50 arc min^2) and on the edge of the 83 arc min^2 4U box. The HEAO MC position for 2A1822−371 is summarised in Table 1.

The first step in identifying the optical counterpart of this source was to carry out multicolour photographic photometry of the above HEAO MC location. The Cerro Tololo Inter-American Observatory 1 m telescope was used on 28–30 April 1978 with the Carnegie Image tube camera. B and R filters were used which combine with the S20 photocathode to give a spectral response closely approaching the Johnson standard colours (the U filter was not used in this case because of scattered moonlight). Enlargements of the B and R plates are shown in Fig. 1, with the HEAO MC X-ray source location overlaid. The star marked S is clearly extremely blue when compared with all neighbouring stars. Subsequent spectrophotometry of star S was carried out 3–4 May UT, using the CTIO 4 m telescope and silicon intensified target (SIT) vidicon, providing digital readout. The very blue nature of the spectrum was readily confirmed, but accurate photometric magnitudes were difficult to ascertain because of poor seeing conditions. However, we estimate magnitudes of $V\sim16.29$ and $B\sim16.24$, with errors of 0.25, and a colour index $(B-V)=-0.05\pm0.1$. Intense emission lines of the λλ4640–4650 CIII/NIII blend and λ4686 He II were easily visible in ~10-min observations, with measured equivalent widths of 1.9 Å for CIII/NIII and 2.8 Å for He II. A

systematic uncertainty ±10% in these equivalent widths arises from the estimation of the continuum level. Given the location of this star within the HEAO MC error box, the very blue nature of the spectrum and the presence of emission lines characteristic of X-ray binary systems (see ref. 5), we consider the identification of this X-ray source to be secure.

As the X-ray spectrum of this source has been shown to be relatively hard (energy spectral index $\alpha \sim 0.7$, with hydrogen column density $N_H \sim 8.10^{22}$ atoms cm^{-2}) (ref. 6), a search for X-ray and/or optical pulsations may be worthwhile.

4U1254−69[3]($l^{II} = 303°$, $b^{II} = -6°$): data from 4U1254−69 (2S1254−690) were accumulated early in the HEAO mission, from 24 orbits between 17 and 19 August 1977 UT. The source was detected at 12σ above background in MC1 and 14σ in MC2, with a measured flux of ~6 UFU (2–6 keV), to be compared with previously catalogued values of 23.2 UFU (2–6 keV) (ref. 3) and ~25 UFU (2–11 keV) (ref. 4). The source was thus considerably weaker than in previous observations; variability is clearly indicated by a factor of 4, as reported from OSO 7 observations[6]. This galactic source has been accurately positioned by SAS 3 and Fig. 2 shows the overlay of our MC error box (diamond) and the 25 arc s radius SAS 3 circle[4] on our CTIO 1 m B plate. The coordinates for the MC error box for 4U1254−60 are shown in Table 1.

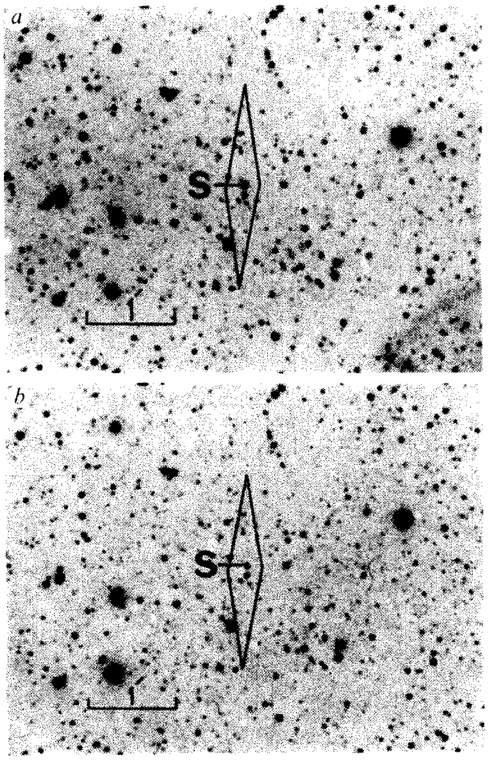

Fig. 1 Finding chart for optical counterpart to 2A1822−371. HEAO MC position (diamond), shown superimposed on our CTIO 1 m B (*a*) and R (*b*) plates. Star S is the optical candidate, discussed in the text. North is up and east to the left is both Figs 1 and 2.

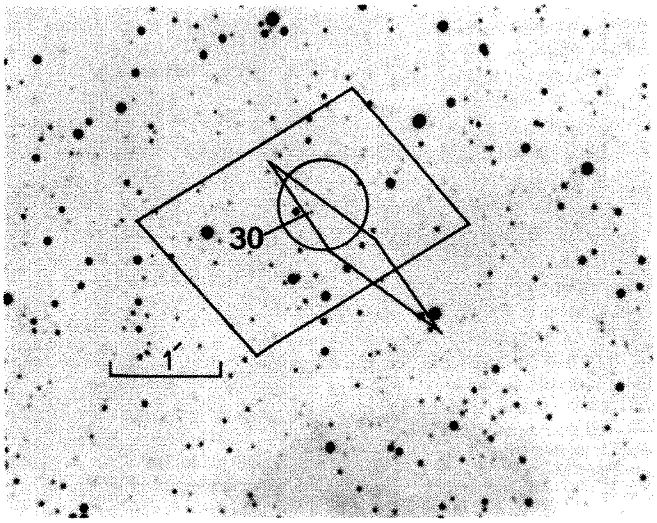

Fig. 2 Finding chart for the optical candidate to 4U1254−69, taken from our CTIO 1 m B plate. The HEAO MC position is the diamond, the circle is the SAS 3 position[4], and the rectangle is the 4U position[3]. The optical candidate is the star labelled '30'.

Using the same equipment described above, U, B and V plates of the 2S1254−690 field showed star 30 of Dower *et al.*[4] to be relatively blue compared to other stars. Estimated magnitudes from our Vidicon observations are $V = 19.09 \pm 0.1$ and $B = 19.24 \pm 0.1$. Spectra of star 30 were taken on 2 and 3 May 1978 UT, which were summed together (~2.7 h integration time) to reveal the λλ4640–4650 CIII/NIII blend with an equivalent width of 5.4 ± 1 Å. As star 30 is within both the SAS 3 and HEAO MC error boxes, we again consider this star as a probable optical identification.

Because of the strong UV excesses observed in these two objects, and their relatively high galactic latitude, neither is likely to be substantially reddened. Thus, it is extremely unlikely that they are early type systems (for example, OB supergiants such as Cyg X-1) as this would imply a distance of ~100 kpc and corresponding X-ray luminosities $\sim 10^{39}$ erg s^{-1}. Given the low reddening, we may compare their X-ray-to-optical luminosity ratios, L_X/L_{opt} with those of other known X-ray counterparts. Taking the bolometric corrections to be zero for simplicity and consistency, and converting to energy units[7], we find L_X/L_{opt} to be ~600 for 4U1254−69 and ~25 for 2A1822−371. Using the same procedure, Sco X-1 has an L_X/L_{opt} of ~900. (The observed colour of 4U1254−69 is very similar to that of Sco X-1; indeed, it may be even more blue.) Thus, 4U1254−69 is remarkably similar to Sco X-1 in this respect, whereas 2A1822−371 is different by more than an order of magnitude. Bolometric corrections are unlikely to account for this effect as the colours of the candidate objects are broadly similar. We suggest that much of the optical luminosity of 2A1822−371 originates in the normal star. The smaller equivalent width of the CIII/NIII blend in 2A1822−371 supports this interpretation.

Assuming the same luminosity for 4U1254−69 as for Sco X-1 ($\sim 4 \times 10^{36}$ erg s^{-1}, 2–10 keV) and a distance to Sco X-1 of 500 pc, we may estimate the distance of 4U1254−69 to be ~10 kpc. As far as we can tell from present observations this system has an optical spectrum similar to that of the steady component of the optical–X-ray burster MXB 1735−44 (refs 8, 9), and colours similar to those of the 7.7 s optical–X-ray pulsating source 4U1626−67 (refs 10, 11).

Interpretation of tails of X-ray bursts

ALCOCK AND HATCHETT[1] recently proposed that the tails of X-ray bursts[2,3] observed during burst decay (time scales typically tens of seconds) are due to the small-angle scattering of the original pulse of X rays on interstellar dust grains. To produce the desired tails, and obey constraints set by optical interstellar reddening data, their model uses grains with a typical size of ~3 μm. Here we give four independent reasons which rule out their model (see also ref. 3).

(1) Bursts from one source in general are similar to one another[2,4]. However, a burst is sometimes detected with a tail much longer (already pointed out by Alcock and Hatchett) or shorter than is typical for that source. This has been observed for example in bursts from MXB1837+05 (SAS-3, unpublished data) and MXB1728−34 (ref. 5) where the minimum duration of the tails was a few seconds, the maximum ~100 s.

Because of the low interstellar reddening of the globular cluster NGC6624, Alcock and Hatchett conclude that the tails of the bursts from MXB1820−30 in this cluster cannot be explained by their model but are intrinsic to the source. Additional evidence for this conclusion is contained in a series of bursts from MXB1820−30, reported by Clark *et al.*[6]. The tails in the bursts became gradually shorter and the last few bursts showed hardly any tails at all. (The tail duration gradually decreased from ~25 s to <10 s). Therefore, a large part of the tails in bursts from these sources must be intrinsic to the source.

(2) Different kinds of bursts are emitted by MXB1730−335 (Rapid Burster)[7]. Besides the Type I bursts, the Rapid Burster also emits Type II bursts, whose spectral evolution is very different in that the softening during burst decay is much less pronounced than in the Type I bursts[7,8]. If the mechanism proposed by Alcock and Hatchett were to explain the tails of the Type I bursts such softening tails should also be observed after these Type II bursts, but they are not.

(3) Furthermore, in spite of the large distance and interstellar reddening[15] of MXB1730–335 a superposition of 12 small Type II bursts by Ulmer *et al.*[16] shows that these bursts do not have tails longer than ~2s. This observation alone shows that the tails caused by interstellar scattering have a duration $\leq$2s for the Rapid Burster.

(4) According to Alcock and Hatchett the optical depth τ_X for scattering of X rays on 3-μm grains has to be small. Hence, the energy observed in the tails of X-ray bursts is proportional to τ_X (see their equation (16)). We make the reasonable assumption that the distribution of the large grains follows that of the small ones (which are responsible for the interstellar reddening). Most of the heavy elements in the interstellar medium are probably locked up in grains[9]. Therefore, according to this model, one would expect a positive correlation between the relative strength of the burst tails and the interstellar absorption. The latter is commonly expressed in terms of the equivalent interstellar column density of hydrogen $N_{\rm H}$. We tested this prediction by comparing the observed values of $N_{\rm H}$, as obtained from fits to the burst spectra[4] with the ratio ε of the energy in the burst tails to the total burst energy. In those cases where optical evidence is available on the interstellar reddening (MXB1659−29; 1735−44 and the galactic centre burst sources)[10–12] good agreement exists with these $N_{\rm H}$ values, using a relationship between $N_{\rm H}$ and E_{B-V} (see refs 13 and 14). It is somewhat ambiguous to determine where the tails start, but this is of no consequence; the range of values of $N_{\rm H}$ is at least a factor of 10, and this is much larger than the uncertainties introduced by the above ambiguity.

There is no correlation between ε and $N_{\rm H}$ for the 10 burst sources studied previously[4]. The values of ε for the sources with $N_{\rm H} \leq 10^{22}$ cm^{-2} range from 0.35 to 0.65. For sources with $N_{\rm H} > 10^{23}$ cm^{-2}, ε ranges from 0.3 to 0.5. These results clearly exclude that the tails are the result of grain scattering, because in that case we would expect values of ε to be approximately proportional to $N_{\rm H}$.

It may be argued that, as dust particles approximately midway between the burst source and the observer dominate the scattering mechanism, this lack of correlation reveals local concentrations of dust around some of the burst sources. In that case the typical value of the 'non local' column density is $\leq 10^{22}$ cm^{-2}, corresponding to interstellar extinction values of $\leq$4 mag. According to Alcock and Hatchett this is insufficient to produce a significant observable effect.

The model of Alcock and Hatchett (although it may work at different time scales and lower intensity levels) does not account for the observed tails of X-ray bursts. These tails are predominantly intrinsic to the X-ray burst mechanism.

We thank Dr Alcock for useful discussions. This work was supported in part by NASA. J.v.P. is on leave from the Astronomical Institute, University of Amsterdam

A possible practical application of heavy quark physics

A POSSIBLE method for storing very large amounts of useable energy within small volumes is described here. Our proposal is based on the existence of two new, virtually stable, forms of matter that annihilate each other with enormous energy release, but neither of which annihilates ordinary matter (and can thus be stored easily). The existence of these new forms of matter is suggested[1,2] by the phenomenology of heavy quarks and also by a large class of widely discussed unified field theories.

It has been proposed[1,2] that the b quark, the constituent of the T meson[3-5], might be a colour sextet and as such probably be absolutely stable. The possible absolute stability of the b quark has also been explored from a different viewpoint[6-8]. We assume[1,2,6] that the electric charge of the b quark equals $-\frac{1}{3}$ times that of the proton. The b quark carries colour and is therefore confined inside colourless hadrons, that is, observable baryons and mesons. The lightest baryons containing a b (or $\bar{b}$) quark are then $B^+ = buu$, $B^0 = bud$, and the lightest mesons are $M^+ = \bar{b}u$ and its antiparticle $M^- = b\bar{u}$. Being each other's antiparticles M^- and M^+ have the same mass: $m_{M^+} = m_{M^-}$, while the B^+ and B^0 masses differ: $m_{B^+} \neq m_{B^0}$. For $m_{B^+} < m_{B^0}$ and $|m_{B^+} - m_{M^-}| < m_p + m_{\pi^+} \simeq 1{,}078$ MeV the hadrons B^+ and M^+ are absolutely stable and B^0 will undergo β-decay. Conversely, for $m_{B^0} < m_{B^+}$ and $|m_{B^0} - m_{M^-}| < m_p \simeq 938$ MeV, B^0 and M^+ are absolutely stable. Standard quark model reasoning strongly suggests the validity of these meson–baryon mass-difference inequalities. Thus the meson M^+ and one of the baryons, B^+ or B^0, are expected to be stable. Whichever baryon is stable (B^+ or B^0) the following three observations apply: (1) neither M^+ nor B^+, B^0 contain $\bar{u}$ or $\bar{d}$ antiquarks and therefore do not annihilate ordinary matter; (2) the positively charged hadrons M^+ and B^+ can form hydrogenoid atoms, which we denote $\mathcal{M}(M^+e^-)$ and $\mathcal{B}(B^+e^-)$, with ordinary negative electrons. These electrically neutral atoms are stable and, as they contain electrons rather than positrons, they do not annihilate ordinary matter either. Hence they may participate in ordinary chemical reactions; (3) M^+ contains one $\bar{b}$ but B^+, B^0 each contain one b quark, so that M^+ can annihilate with both B^+ and B^0.

Several intriguing new possibilities arise. The most attractive one is to assume first stable M^+ and B^+. The resulting hydrogenoid gases $\mathcal{M}_2$ and $\mathcal{B}_2$ may be stored in conventional containers and transported separately, or the compound $\mathcal{M}\mathcal{B}$ may be formed and transported itself. Other more complex chemical compounds would certainly exist. These two new forms of matter $\mathcal{M}$ and $\mathcal{B}$ can be induced to annihilate with considerable release of energy, ~10 GeV per reaction, with typical nuclear cross sections.

The case of a stable M^+ and B^0 is more subtle. Perhaps the B^0 can be attached to a conventional nucleus forming an exotic isotope. For example, if a stable heavy deuterium consisting of B^0p^+ exists, then the discussion of the preceding paragraph applies with $\mathcal{B}$ replaced by $B^0p^+e^-$. Other stable or long lived quasi-stable isotopes may exist. If no stable nuclei containing B^0 exist, then this substance would have to be contained by itself, perhaps using a 'magnetic bottle' with a field of non-uniform gradient exploiting the B^0 magnetic moment. In this case there would no no Coulomb barrier to overcome in initiating annihilation reactions.

All these possibilities seem to be within the realm of conventional technology. Stable quarks would, therefore, offer the possibility of storing very high (useable) energies within small volumes. The technological possibilities are self-evident. It is, as we have found, an inexpensive device to store antiprotons.

We emphasise that experimentally both the existence and the stability questions for the B^{0+} and M^+ hadrons are still open. A further problem is to provide sufficient amounts of B^{0+} and M^+ matter in a reasonable time interval. Nevertheless, the prospect of this new energy source is worth pointing out at this time.

Finally, should the b quark not be absolutely stable or sufficiently long lived, heavier quarks may exist which are.. If carrying $-1/3$ or $+2/3$ proton electric charges, any such quark would be as good in the applications envisaged here.

Since we submitted this note two experimental searches[9,10] for stable hadrons in the 4–10 GeV c^{-2} mass range have yielded negative results, thus making the existence of stable b-quark-containing hadrons highly unlikely. One may have to wait for higher quark species. We have also learned of a paper of H. Fritzsch[11], in which the results given in refs 1, 2 are independently obtained.

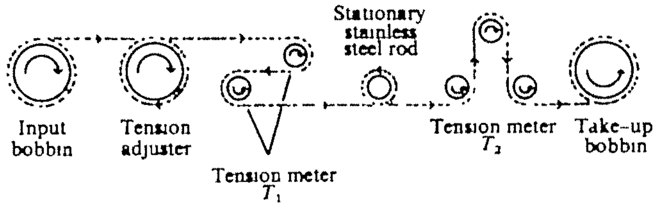
Dyeing increases the friction of synthetic polymer yarns

WE show here that the friction on metal of poly(ethyleneterephthalate) (PET), nylon-6,6 and polyacrylonitrile (PAN) yarns increases when the yarns are dyed, each with a different dye. This phenomenon is well known in the textile industry, but it has only been investigated quantitatively in one case, the friction of dyed wool on metal[1]. Our results show that it is a general phenomenon, and that it is possible to change the mechanical properties of a polymer by the addition of small molecules which have an affinity for the polymer chains.

The PET, nylon-6,6 and PAN yarns were dyed with a disperse, an acid and a basic dye respectively in various conditions (see legends to Figs 2 and 3). The friction of the dyed yarn samples, of the purified but otherwise untreated yarns, and of

Fig. 1 Measurement of yarn friction (see ref 3 pages 189, 210). Dyed and undyed yarn samples were originally wound on bobbins. The yarn passes round a pulley with a ferromagnetic disk at its centre: the input tension of the yarn is adjusted by moving a permanent magnet nearer or further from the disk. Input tension T_1 is measured by a tension meter consisting of two small pulleys one of which is on a spring loaded arm. The yarn passes once round a stationary steel rod 1 cm diameter then over three small pulleys of a second meter: the central pulley is attached to the plates of a condenser, and its capacitance is recorded continuously and calibrated to measure the output tension, T_2. The yarn is wound on to a bobbin at a constant speed of 12.8 m min^{-1}. Pulleys and the rod were cleaned with acetone before each determination



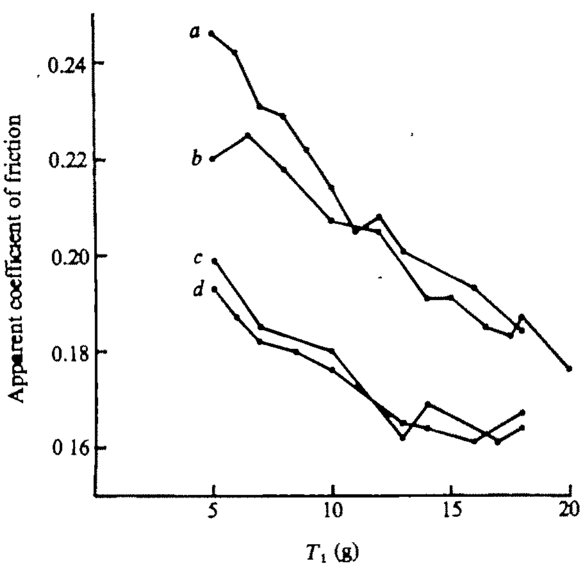


Fig. 2 Decrease in the apparent coefficient of friction of dyed and undyed nylon-6,6 yarn as the input tension is increased: yarn dyed with *a*, 10% and *b*, 7% dye in the dyebath, *c*, undyed yarn, *d*, yarn treated in the same conditions as the dyed yarns but with dye omitted from the bath. Samples of nylon-6,6 yarn (100 m) were purified by soxhlet extraction for 12 h with 60/40 v/v benzene–methanol mixture. The ratio of the dyebath volume to dry weight of the yarn was 30:1. Each yarn sample was immersed in distilled water containing 4% v/wt formic acid for 15 min at 50 °C (all percentages are based on the weight of the yarn). 1% Nylomine Black A-B (ICI), an acid dye, was dissolved in a small volume of the dilute formic acid solution and added to the dyebath, which was raised to 95 °C in 45 min with stirring, and maintained at 95 °C for a further 45 min. The bath containing the yarn was allowed to cool to room temperature. The yarn was rinsed in distilled water and dried at room temperature. Further samples of nylon-6,6 yarn were dyed in the same way in baths containing 2–10% dye (increments of 1%). In the control (*d*), a yarn sample was treated in the same way, except that dye was omitted from the bath. Weight of the yarn, $0.252\ \mathrm{g\ m^{-1}}$, delustred with 0.38% TiO_2.

the yarns treated in the same conditions as the dyed yarns but with the dye omitted from the bath (blank dyebath), were measured using a capstan apparatus (Fig. 1) in which the yarn passes round a stationary stainless steel rod at a constant speed. The apparent coefficient of yarn friction on metal is calculated from the yarn tension T_1 before it passes round the rod and the tension T_2 after the rod.

Assuming that the coefficient of friction of the yarn, μ is related to the frictional force F and the normal force W by:

$$\mu = \frac{F}{W} \tag{1}$$

and assuming that the yarn is inextensible and completely flexible, it can be shown (page 374 ref. 2, page 47 ref. 3) that in the capstan experiment

$$\mu = \frac{1}{2\pi}\ln\left(\frac{T_2}{T_1}\right) \tag{2}$$

It has been shown experimentally that μ determined in this way for a given yarn is not a constant but varies as the input tension T_1 is varied (page 47 ref. 3). μ also depends on the diameter of the rod[3] and on the speed of the yarn[4] This is because equation (1) is not strictly obeyed by polymers sliding on metal, and because yarns are not completely flexible and inextensible[5,6]. The rod used and the speed of the yarn were the same throughout our experiments, and Fig. 2 shows how the apparent coefficient of friction of undyed and dyed nylon-6,6 yarn, calculated from equation (2) alters as T_1 is varied. Dyed and undyed PET and PAN yarns show a similar decrease in the value of μ as T_1 is increased.

The friction of each yarn purified but undyed, treated in a blank dyebath, and treated with various amounts of dye, was compared by calculating the apparent values of μ at two chosen values of T_1. The results (Fig. 3) show that for nylon-6,6, PET and PAN yarns the yarn friction on metal increases as the amount of the appropriate dye in the dyebath is increased (that is, as the amount of dye absorbed by the yarn is increased). The comparison of dyed yarn with two controls (undyed and blank dyebath) suggests that the greater friction of the dyed yarns must be due to the dye absorbed by the yarns and cannot be

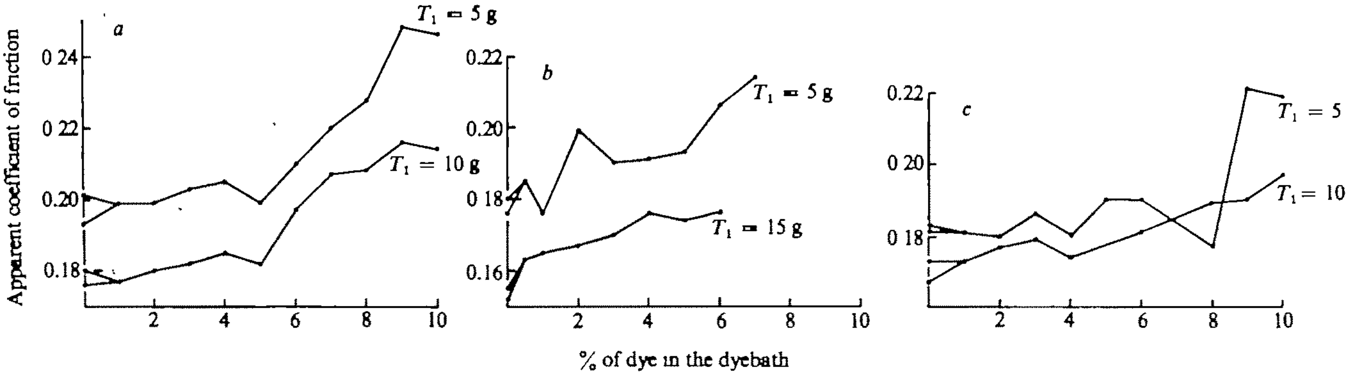

Fig. 3 Increase in the apparent coefficient of friction of nylon-6,6 (*a*), PET (*b*) and PAN (*c*) yarns as the weight of dye in the dyebath is increased. Determinations were made at 5 g and 10 g or 15 g input tension. 100 m samples of all three yarns were purified, dried and weighed as for Fig 2. Nylon-6,6 yarn was dyed as described for Fig. 2. The ratio of the dyebath volume to the yarn weight was 30:1. An aqueous 0.3% solution (v/v based on the volume of water) of Optinol B (Yorkshire Chemical Co.) was adjusted to *p*H 5 with acetic acid and heated to 60 °C A PET yarn sample was placed in it. After 10 min, 0.5% Serilene blue 2G (Yorkshire Chemical) was dissolved in a small volume of the Optinol B solution and added. After stirring for 5 min at 60 °C the temperature was raised slowly to boiling and maintained at the boil for 1 h. The dyebath containing the yarn was allowed to cool to room temperature and the yarn was rinsed in distilled water and dried in air Further yarn samples were dyed in the same way in dyebaths containing 1–7% dye Another yarn sample was treated in the same way in a *p*H 5 Optinol B solution without dye. Weight of the PET yarn, $0.044\ \mathrm{g\ m^{-1}}$; delustred with 0.26% TiO_2 A sample of PAN yarn was wetted with distilled water and put into a dyebath containing 1% acetic acid, 1% sodium acetate, 1% Synacril blue R (ICI) and 1 9% Ataxal LC-RA (ICI) cationic retarder, at 95 °C The dyebath was raised to the boiling point over 10 min. Boiling was continued for 45 min, and then the dyebath containing the yarn was cooled to room temperature and the yarn was removed and rinsed in distilled water. The procedure was repeated using 2% dye and 1.6% retarder, 3% dye and 1 3% retarder, 4% dye and 1.0% retarder, 5% dye and 0.8% retarder, 6% dye and 0.5% retarder, and 7%, 8%, 9% and 10% dye without retarder. A sample of yarn was also treated at the same temperatures for the same times in a bath containing only 1% acetic acid, 1% sodium acetate and 1.9% retarder. Weight of the PAN yarn, $0.124\ \mathrm{g\ m^{-1}}$, delustred with 0.32% TiO_2. For the nylon-6,6 and the PAN yarns the higher value of the apparent coefficient of friction at 0% dye was the value obtained with the purified yarn and the lower value was the value obtained with the yarn treated in a blank dyebath. For the PET yarn the opposite was found.

explained, for example, by the removal of lubricant from the yarns during dyeing, or by deposition of oligomers on the surface of the PET yarn during dyeing.

In the simple adhesion theory of friction, Bowden and Tabor (ref. 2 pages 52, 214) propose that when one material is sliding over another the coefficient of friction μ is equal to s/p where s is the force per unit area necessary to shear the softer material, and p is the pressure at which the softer material ceases to deform elastically and begins to flow plastically (that is, p is the yield pressure of the softer material). Our results imply that in drawn synthetic fibres, dyeing increases the shear strength of the fibres in the direction of the fibre axis more than it increases the yield pressure. This may be a consequence of the preferred orientation of the polymer molecules in the fibre direction. Small molecules, not necessarily coloured, with an affinity for the polymer chains may alter the mechanical properties of a polymer by forming weak, non-covalent crosslinks between the chains.

Horizontal structure of scintillation-producing irregularities in southern mid-latitudes

THERE is little information on the instantaneous macroscopic structure of scintillation regions affecting radio communications from satellites. The horizontal structure of scintillation regions has been studied using one or two orbiting satellites or a geostationary satellite. In these studies the temporal and/or spatial resolutions of the methods were poor which made it difficult to evaluate the latitudinal and longitudinal distributions of scintillations over a short period. The temporal resolution is important as scintillation patches seem to drift with a median velocity of 100 m s^{-1}, changing their position from one satellite pass to another[1]. To overcome these difficulties I have used all the available VHF transmissions (frequency range: 136–150 MHz) from the following non-synchronous satellites (satellite orbit's inclination is given in brackets): six US Navy Navigational Satellites (90°), NOAA 3 and NOAA4 (102°), Nimbus 4 (98°), Nimbus 5 and Nimbus 6 (100°), Copernicus (35°), Geos 3 (102°) and Kiku (47°). Amplitude transmissions from these satellites (positioned at altitudes: 700–1,500 km) were recorded on a continuous basis during the periods of increased scintillation activity: summer (November–January 1976–77 and 1977–78) and winter (May–July 1977). The recording station was situated at Brisbane (27.5° S and 152.9° E geogr. lat and long, and 37.2° S invar. lat). The definition of scintillation index (SI) has been given elsewhere[2].

On occasions scintillation activity coincided with a relatively large number of satellite passes during a period of one hour or less. It was assumed that the position of scintillation patches did not change greatly from the first to the last recorded pass during this time. Figure 1 shows examples of horizontal extents of scintillation patches recorded for closely spaced satellite passes during summer night-time (*a* and *b*) and winter daytime (*c*).

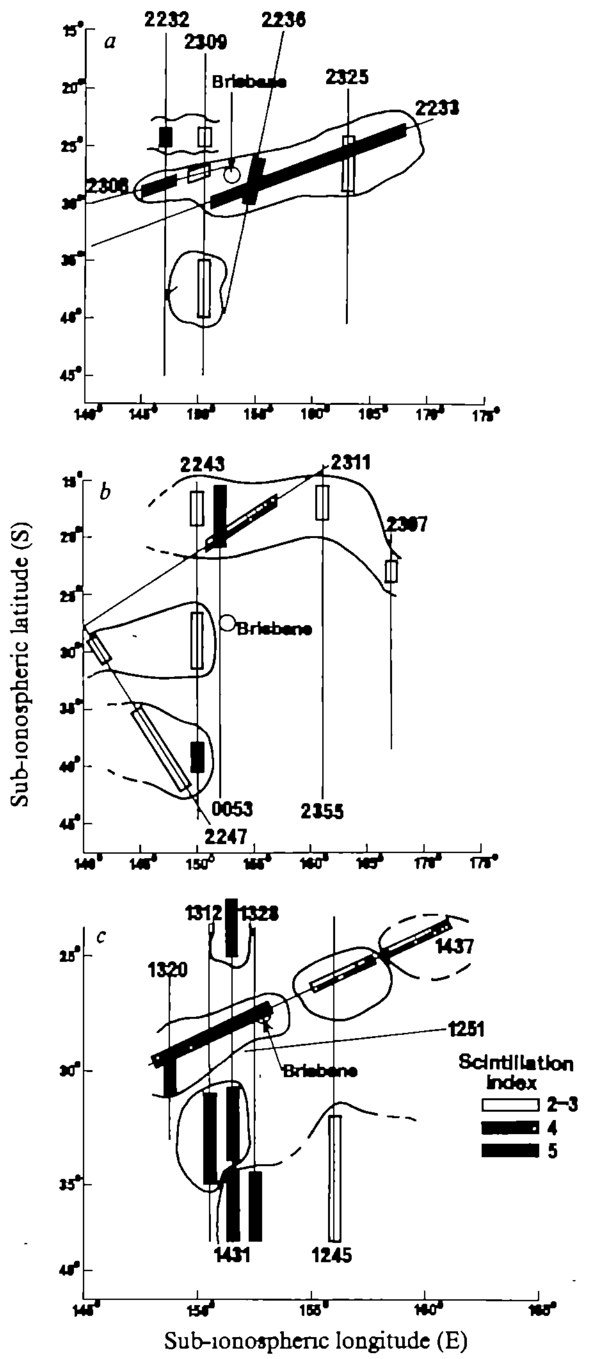

Fig. 1 Examples of sub-ionospheric scintillation regions (rectangulars and curves) derived from amplitude scintillations in the VHF transmissions from orbitting satellites. Thin lines refer to the satellite orbits in the vicinity of the recording station at Brisbane. The numbers indicate the local times (150° EST) of the nearest predicted approaches of satellites. The magnitude of scintillation index (SI) is indicated whenever scintillations are present. *a*, 19 January 1978; $h = 400$ km; *b*, 3–4 January 1977, $h = 400$ km, *c*, 3 July 1977; $h = 100$ km.

Inspection of data from a vertical-incidence ionosonde operating at the same site indicated the presence of intense spread-F and sporadic-E activity coinciding with the periods (*a*, *b*) and (*c*), respectively. From this it was assumed that scintillation-producing irregularities were positioned at altitudes of 400 km (night) and 100 km (day). In Fig 1*a* scintillations in the

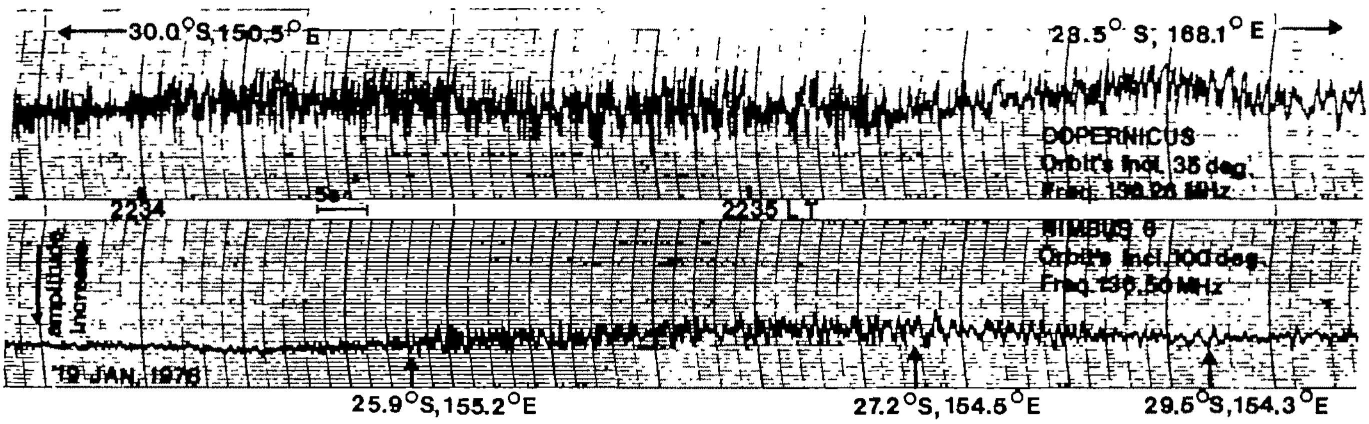

Fig. 2 An example of two simultaneous amplitude recordings of radio-satellite transmissions at frequencies of 136.26 MHz and 136.50 MHz from two orbiting satellites moving mainly in longitude (upper trace) and latitude (lower trace). The sub-ionosphere positions of the limits of scintillation regions are indicated by arrows; the central arrow at 27.2° S and 154.5° E refers to the same sub-ionospheric position for both satellites.

vicinity of Brisbane consisted of an elongated patch extending from about 145° to 170° E longitude. The latitudinal extent was narrower as can be seen from the amplitude data for the north–south passes at 22.36 and 23.25 LT. In particular, two almost simultaneous passes at 22.36 LT (north–south) and 22.33 LT (east–west) revealed a ridge-like formation in scintillations. This can be further seen in Fig. 2 which shows the amplitude scintillation data for these two passes. It is evident that scintillation activity decreased rather rapidly for the north–south pass (Nimbus 6) and continued unbroken for the east–west pass (Copernicus). In addition to the main scintillation ridge two scintillation patches were recorded north and south of the station. The presence of longitudinally extended scintillations is also evident in the second period (Fig. 1*b*) when a sheet-like irregularity was formed north of the station. Two isolated irregular patches were formed west and south–west of the station. Several isolated patches were recorded during daytime in winter (Fig. 1*c*). Once again scintillation causing irregularities had a large longitudinal extent. It is interesting that the irregularity positioned between 150° and 152° E was detected by the east–west pass (14.37 LT) only; no scintillations were recorded in this region for north–south passes at 14.31, 13.28 and 13.12 LT. The phenomenon was not isolated and could also be seen in Fig. 1*a* when scintillation patches recorded for east–west pass at 23.08 LT were not present for two north–south passes at 22.32 and 23.09 LT.

It was possible to obtain 12 records as in Fig. 1 for which at least three satellite passes were recorded with an average time separation of 20 min. In all cases minimum longitudinal extent of scintillations varied from 20° to 30°. Latitudinal extents varied from 3° to 12°, the median value being from 4° to 6°. The horizontal extents of scintillation patches recorded for low orbit's inclination satellites (east–west passes) were several times larger than those for polar orbit's satellites (north–south passes).

Similar results for scintillation occurrences in southern mid-latitudes were also reported from a single polar orbit's satellite transmitting at 20 MHz (ref. 3). It was found that night-time scintillation-producing irregularities occurred in patches with the horizontal extents of 2° to 3° in latitude and more than 15° in longitude. The presence of longitudinally extended irregularity sheets was also reported from a satellite scintillation experiment in Alaska[4]. The ridge-like enhancement in scintillations was associated with the occurrence of the auroral to subauroral transition boundary in the ionospheric total electron content. My results indicate, however, that the sheet-like irregular regions are not limited to a particular spatial position but can occur at various latitudes near the recording station. This might point to a hitherto unrecognised structure of irregularities characterised by a preferential longitudinal extent. A possible link can be established between this type of irregularities and formation of mid-latitude stable auroral red arcs (SAR) which are aligned in longitude with constant L-shell. Their latitudinal extent is limited between 2° and 4° (ref. 5). There is evidence that SAR are associated with ionospheric scintillations in the UHF range of radio-satellite transmissions[6].

Detection of ^{14}C using a small van de Graaff accelerator

THERE have been several recent reports of the detection of ^{14}C in modern carbon samples using large van de Graaff accelerators[1-3] and cyclotrons[4] as mass spectrometers. The attraction of using such systems is the possibility that very small samples (~5 mg) might be quickly and accurately dated. We have considered the design criteria for a mass spectrometer incorporating a

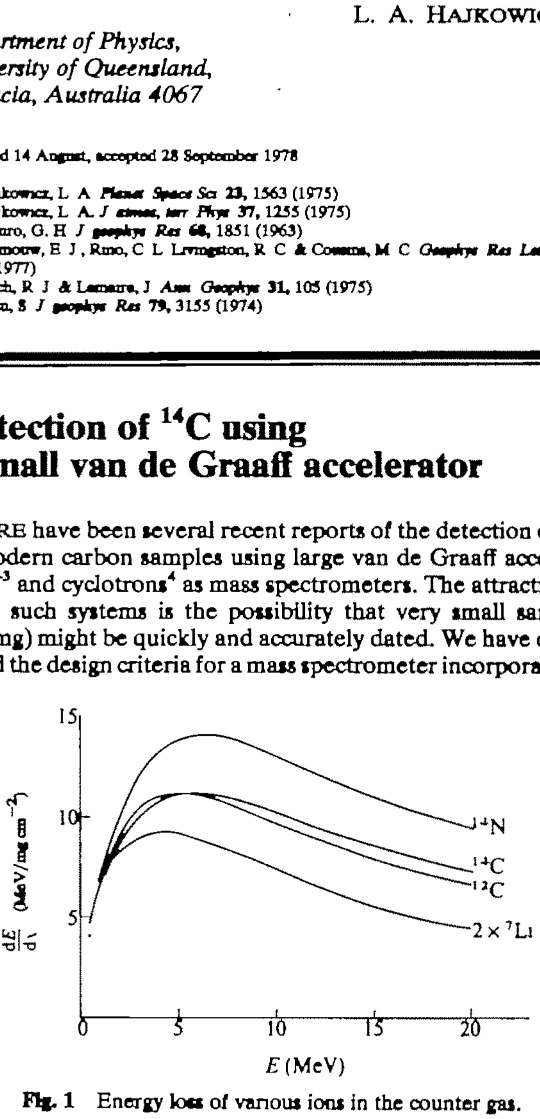

Fig. 1 Energy loss of various ions in the counter gas.

tandem van de Graaff accelerator to be built specifically for carbon dating and in this letter we present data which show that the measurements are possible using much smaller and simpler systems than those discussed previously.

The most important system parameter to establish is the required terminal voltage as this will set the size and cost of the facility. The chief advantage of using a high energy mass spectrometer is that ions can be uniquely identified by measuring their energy and specific energy loss. The energy loss depends on the energy, mass and charge of the nucleus as shown in Fig. 1 (ref. 4). It can be seen from Fig. 4 that at low energy this identification becomes extremely difficult. In practice a clean measurement can be made for carbon ions if they have an energy of more than 5 MeV after passing through the dE/dx part of a gridded ionisation detector[5]. If the counter is set to give two dE/dx measurements with about 1 MeV loss in each, and if there is about 1 MeV loss in the counter window and in the poor field region near the window, then the minimum safe energy is 8 MeV. Figure 2 (ref. 6) shows the charge state fractions for ^{14}C ions being stripped in thin carbon foils. It can be seen that at 2.5 MeV the stripping to the 3^+ charge state reaches a maximum so that a satisfactory design would have the tandem terminal at 2.5 MV producing 10 MeV ^{14}C^{3+} ions.

Furthermore recent measurements at Rochester have shown that doubly charged metastable molecular ions of mass 14 exist whose lifetimes are long enough for them to introduce a considerable background. This problem can be avoided by selecting the 3^+ charge state, for which the lifetimes of metastable ions are known to be very short.

We have demonstrated that 2.5 MeV is a suitable choice of operating voltage using the experimental system shown in Fig. 3.

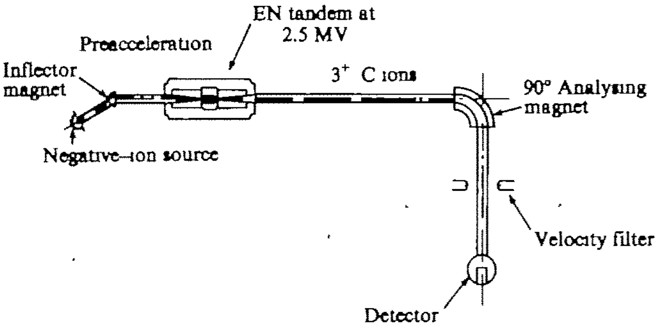

Fig. 3. Beam transport system for the ^{14}C mass spectrometer

The carbon samples were introduced into a reflected beam sputter source[8] in the form of graphite pellets made by pyrolising methane at a pressure of about 500 torr. In this type of ion source a beam of caesium ions, produced by surface ionisation, is accelerated and then focused on to a pellet from which some of the sputtered particles emerge with a negative charge. The intensity of our ^{12}C$^-$ beam was of the order of 5 μA and the intensity of the mass 14 beam was found to be about 3 nA, consisting mainly of ^{12}CH$_2^-$ and ^{13}CH$^-$ and a small fraction of ^{14}C$^-$. For a modern carbon sample, this fraction corresponds to about 37 ^{14}C^{3+} ions per second arriving at the detector. After acceleration and stripping the beam was momentum analysed to select the 3^+, mass 14 beam with a resolution of 1 : 10^3. A Wien filter with a velocity resolution of 5% removed most of the ions which had the correct magnetic rigidity but which suffered charge exchange outside the gas stripper. The resulting ions were detected in a gridded ion chamber filled with isobutane at

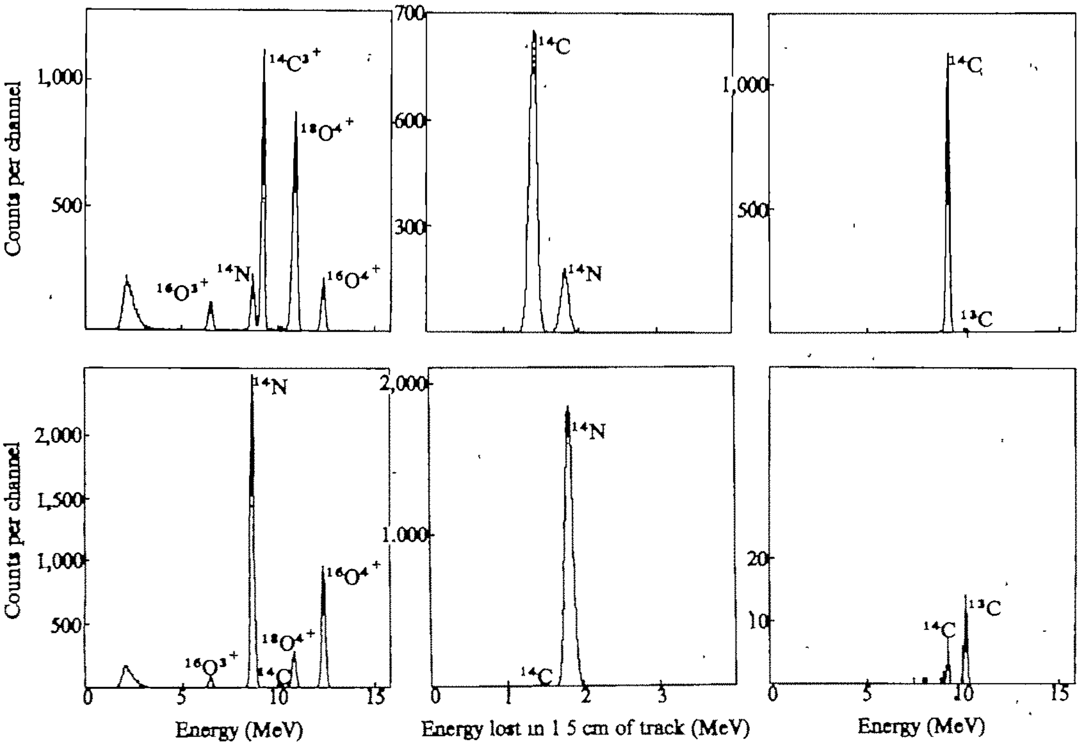

Fig. 4 Energy and energy loss spectra obtained for modern (top line) and old (bottom line) carbon samples. Left, total energy spectrum for carbon; centre, ΔE_2 for ^{14}N+^{14}C; right, total energy spectrum for carbon ions.

20 torr. The anode of this chamber is split into three sections running normal to the ion trajectories so that two measurements of energy loss (dE/dx) could be made in addition to the total energy. For each ion entering the detector, the ionisation measurements were digitised and recorded on magnetic tape using an on-line computer. The data were then processed to produce various spectra which allowed the ^{14}C count to be determined. Further experimental details may be found in ref. 9.

Typical data for modern and old carbon samples are shown in Fig. 4. It is clear from the energy spectra that the energy resolution obtained (150 keV FWHM) is sufficient to separate the carbon isotopes cleanly. The dE/dx resolution is sufficient to separate the ^{14}N group from the ^{14}C. Interestingly, the nitrogen group is quite intense at these energies. It was established by scanning the terminal voltage that this nitrogen comes from injected NH^- ions which charge exchange somewhere in the accelerator tubes. By observing that there was no shift in the dE/dx peak for the ^{14}C groups from old and new samples we could rule out a significant contribution from $^{13}CH^{3+}$ or $^{12}CH_2^{3+}$ molecules in this measurement. The background from misidentified particles was less than one count per day.

Our measurements indicate that errors due to cross contamination of samples in the ion source are less than 0.1%. Improved ion sources can produce over 100 μA of $^{12}C^-$ ions, so that 0.1% counting statistics could be achieved in a few hours. In order to make abundance measurements to this accuracy, however, it will be necessary to monitor closely the source output and the transmission through the accelerator. We propose to achieve this by pulsing the injection system to accelerate the ^{12}C and ^{13}C beams for a few microseconds every millisecond. These beams would be measured in separate ports on the analysing magnet. In addition the ion source will alternate between the unknown sample and a standard. It should then be possible to date accurately small archaeological or environmental samples or the products of laser enrichment as discussed in the previous article.

Enrichment of ^{14}C and radiocarbon dating

THE very low natural abundance of ^{14}C (10^{-12} times that of ^{12}C) and its exponential decrease in time require exceptionally sensitive methods for its measurement in the dating of archaeological and environmental samples. Present methods count β emission from the nuclear disintegration and so require substantial samples (1–5 g), long count times (1–3 d), and great attention to ensure a low level background. Nevertheless, they have been developed to a point where a reproducibility of 0.025% (one standard deviation) has been attained.[1] Here we describe experiments in which dilute ($^{14}C = 10^{-4} \times {}^{12}C$) samples for CH_2O were enriched by a factor up to 100 by selective photolysis of an individual rotational line in the UV spectrum with a tunable laser. Full details of the experiment will be published elsewhere[2]. This letter summarises the process and develops its relationship to existing and potential carbon dating methods.

Formaldehyde is a convenient molecule for isotopically selective photolysis because it has a well-resolved spectrum in the near UV with a quantum yield for dissociation of near unity. From 350 to 340 nm dissociation is entirely due to $CO+H_2$, whereas from 330 to 290 nm about 30% of the quantum yield is to $H+HCO$ (ref. 3). If the radicals are not scavenged the enrichment can be reduced. Enrichment takes place when the molecule is photolysed at a frequency where the $^{14}CH_2O$ absorption cross section is much greater than that for the other isotopes. Previous work[4] has shown that a tunable laser with modest bandwidth (~20 GHz) could enrich ^{12}C from a mixture of ^{12}C and ^{13}C formaldehyde, and that enrichments of up to 30 could be achieved for some C and O isotopes using ion lasers[5]. Because of the vibrational band envelope structure of the electronic transition in CH_2O it is to be expected that enrichment of a heavier isotope from a mixture will be more difficult, and a necessary preliminary to the enrichment described here was a high resolution survey of the absorption spectra of $^{14}CH_2O$ and $^{12}CH_2O$ throughout most of the spectral region of 290–350 nm.

Absorption spectra were obtained with a tunable, frequency doubled dye laser (either a Hänsch type N_2 pumped laser, or the Chromatix CMX-4) transmitted in two passes through 2–3 m of 33% $^{14}CH_2O$ at about 3 torr, and through 6 m of CH_2O at 10 torr. The laser frequency bandwidth was around 3 GHz ($0.1\ cm^{-1}$). More than 30 $^{14}CH_2O$ lines were noted in which the absorption cross section ratio was measured to be greater than 50, and also where the $^{14}CH_2O$ absorption cross section itself was greater than $5 \times 10^{-20}\ cm^2$. Figure 1 compares high resolution spectra of $^{12}CH_2O$ and $^{14}CH_2O$ where such an enrichment line is to be found (at 331.41 nm). The absorption ratio at the spectral resolution used here is 300 ± 100. The majority of these enrichment lines were in the region 318–340 nm despite the fact that at longer wavelengths the isotope shift is less.

Enrichment was carried out by photolysing a sample of CH_2O containing 0.01% $^{14}CH_2O$ in a 3-m cell with two passes for 1–2 h: laser power was typically 0.2–0.5 mW. The CO so produced, in micromole quantities, was collected by trapping with liquid helium, estimated by gas chromatography, and measured for radioactivity with a gas conductivity meter. The specific activity was compared with that obtained from the CO produced by photolysing an equivalent sample of CH_2O with broad band light (mercury lamp), and the ratio of the two specific activities gave the enrichment factor. Enrichment was performed at 318.59 nm and 326.99 nm. The latter wavelength corresponded to the best projected enrichment value and enrichment in the region of 100 was achieved without any attempt at radical scavenging. Improvements to this figure can be expected through minimising pressure broadening effects and improving the laser bandwidth and frequency stability.

As ^{13}C constitutes 1% of natural C, it will become the predominant isotope at enrichments (with respect to ^{12}C) of over 100. Therefore to increase the proportion of ^{14}C in a sample beyond a factor of 100, enrichment with respect to ^{13}C must also be achieved. While frequencies for the optimum enrichment against one isotope will not coincide with those for the other, a study of the overlap of ^{12}C-, ^{13}C- and ^{14}C-H_2O spectral lines shows that substantial enrichment (>10) against ^{13}C can occur simultaneously with high enrichment (≥ 100) against ^{12}C.

We now assess the relevance of laser enrichment to ^{14}C age determination. Enrichment by thermal diffusion of massive samples is already carried out at several radiocarbon laboratories; its requirements of very large samples (~40 g), long

0028–0836/78/0276—0255$01.00

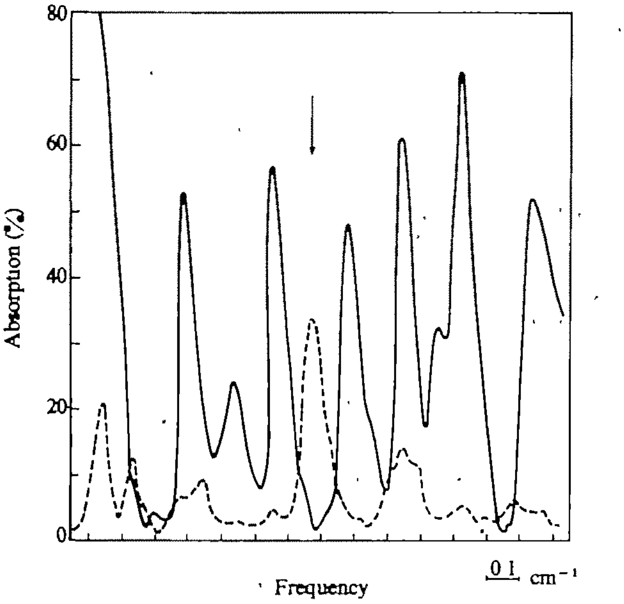

Fig. 1 Comparison of high resolution spectra of $^{12}CH_2O$ and $^{14}CH_2O$. $^{14}CH_2O$ absorption has been reduced by 30 to fit on the same scale.

times (3 weeks) and low enrichment for sufficient product (factor of four) restrict its application to samples too old to date by standard methods (>40,000 yr, <70,000 yr).

First we consider the practical implications for a laser enrichment system; formaldehyde is relatively easy to prepare, either by the catalytic reduction of CO_2 to methanol, followed by catalytic oxidation, or by the mercury photosensitised reaction of H_2 with CO (ref. 5). Its propensity to polymerise requires that the monomer be stored at 77 K, or at low pressure (<20 torr) in apparatus free from adsorbed water. The photolysis product, CO, is easily extracted in distilled form from the photolysis cell.

The major limitation is the laser energy required to enrich macroscopic amounts of sample. A $^{14}CH_2O$ absorption cross section of 10^{-19} cm^2 implies that a photon flux of 0.7 mW cm^{-2} will convert 20% of the $^{14}CH_2O$ per hour. This was confirmed in our photolysis experiments. In a carefully designed system it is clear from the effect of the laser linewidth on the measured isotopic cross section ratio that a bandwidth of less than the Doppler width (of 2 GHz) is desirable. To photolyse 50% of the ^{14}C in a 1 g sample, a laser energy in the region of 100 mW hr is necessary. In general the process is likely to be most useful when extracting 20–50% of the ^{14}C, as the enrichment factor starts to fall once the ^{14}C is significantly depleted. In practice we may expect the required energy to be higher by perhaps a factor of two. Where accurate knowledge of the enrichment factor is needed (for example, in the dating of 'young' samples), simultaneous photolysis of a calibrated standard in a separate cell can be carried out. In this way variations in laser frequency and bandwidth are compensated and do not cause systematic changes in the enrichment factor. The design of the laser will depend on the power expected. It is unfortunate that, despite a careful search, no lines for enriching ^{14}C were found to coincide with the frequencies available from high powered rare gas ion lasers. While it is possible that new lines will be available, the chance of coinciding with an enrichment line is very small. Possible tunable laser systems include Raman shifted tunable rare-gas halide lasers, or dye lasers either frequency doubled following pumping by a high repetition rate Cu vapour laser or a high power cw ion laser, or the direct lasing at 330 nm of p-terphenyl, pumped by a KrF laser.

There are three possible approaches to ^{14}C abundance measurements—counting ^{14}C atoms or ions after mass filtering, counting the nuclear disintegrations and measuring the half life, or integrating the radioactivity over a period of time. Only the second method has been used so far for the routine production of dates.

As 1 g of modern carbon has a disintegration rate of 15 d.p.m. counting methods require samples in the 1–5 g range to be counted for 1–2 d for adequate statistics. The advantage of enriched samples is in permitting much smaller counters to be used, thus reducing the background level (which increases with the counter volume). For a modern sample a minimum of 0.5 g is required to accumulate 1% statistics in 24 hours (with negligible background), and laser enrichment could offer little advantage. (The slight gain in accuracy by reducing the background would be offset by inaccuracies in estimating the enrichment factor). But there is a gain for older samples, provided sufficient material can be processed. Consider the enrichment of a 5 g sample of 38,000 yr age. If 25% of the ^{14}C is extracted, and the typical background of 1 c.p.m. is reduced to 5 counts per hour, in 24 hours of counting the background is estimated to 10% statistics, while the signal is estimated to 4%, and the overall statistical error is about 8%, or 1% of the date. The processing of 5 g samples is rather beyond present laser power capabilities, but it would not be unreasonable to expect these to increase by a factor of five in the next few years.

Integrating the radioactivity, for example in a photographic emulsion or thermoluminescent dosimeter, frees the sample from expensive counting apparatus and allows integration for a long period. In natural samples the dose rate is comparable to the cosmic ray and residual dose backgrounds, but 100-fold enrichment would reduce these to negligible levels[6]. The sample size needed can be very small, and so is much better suited to currently available lasers. For example, 10 mg of carbon enriched to 0.1 mg (from a 40 mg sample) gives a 1 mrad dose in three weeks to a conveniently small quantity of phosphor (Dy:$CaSO_4$), and while thermoluminescent measurements are unlikely to have the accuracy of conventional counting the advantages of this approach in economy and speed are worth pursuing. In principle the same advantages apply to track counting in emulsions[7], where the level of background tracks can be made negligible and therefore do not require sophisticated discrimination.

If all the ^{14}C atoms are detected, 1 mg of modern carbon contains about 4×10^7 atoms. While the degree of mass filtering from ^{12}C and ^{13}C is enormous, mass spectrometric systems could have total efficiences in the region of 5–0.1% so that a requirement for modern carbon of 1 mg samples is reasonable. Such accuracy should make it possible to date many new materials, such as CO_2 in glacier cores, foraminiferas in ocean cores, carbon in archaeological iron and single seeds. The first serious attempt[8] to detect ^{14}C mass spectrometrically was made with a two-stage mass spectrometer of $^{14}C^{15}N^-$. This failed because of high backgrounds from molecular impurities at this mass. The isotope enrichment process described here was originally designed for a novel mass spectrometer system, following an idea of Bennett[9]. Bennett proposed a beam/foil conversion of C^+ at 30 keV to C^-, with mass filtering of both charge states, thus eliminating background due to the presence of ^{14}N (where the probability of forming metastable N^- is extremely low) and molecular species.

Other methods using small samples have demonstrated the advantages of accelerating C^-, stripping to C^{n+}, and accelerating to energies above 10 MeV where their detection signatures can be better identified[10,11]. Another similar proposal is to accelerate C^{2+} in a cyclotron[12]. These methods imply an initial beam current of the order of 1–50 µA, a final count of 10^4 on modern carbon, and a run time of an hour or so. Results with the tandem van de Graaff accelerator show that enrichment is not necessary for the dating of recent samples. This is clearly shown in the accompanying article[13], which presents results of van de Graaff mass spectrometric detection of ^{14}C with an experimental arrangement that would be suitable for the operation of a small facility dedicated to ^{14}C dating. However, it is in extending the age to which samples can be dated that the technique of isotope enrichment will be most important. An enrichment of 100–

300 corresponds to a decrease of 37,000–45,000 yr in age; with the likely limit for direct measurement in the 50,000–100,000 yr region, a very significant extension to dating possibilities can be made. The integrity of the sample may perhaps be the ultimate limit; at 10^5 yr, contamination by 1 p.p.m. of modern carbon will double the ^{14}C content, or make the apparent age 6,000 yr younger. Fortunately with small samples (the minimum sample at this age to give 100 counts with the maximum total detection efficiency of 5% expected in the tandem van de Graaff is 50 mg) it is easier to ensure that the sample has been stringently purified. For example, that extracted collagen from bone has the appropriate (highly distinctive) amino acid decomposition. It has been pointed out[12] that a large error in the abundance determination for samples many half lives old leads to a quite acceptable error in the date, because of their exponential relation, and so 100 counts is more than adequate to estimate a reliable date, provided the background is low enough.

We therefore expect laser enrichment to make a major contribution enabling carbon dating to be reliably applied well into the last interglacial period, once the new mass spectrometric methods have been fully developed. Pre-enrichment on recent samples would permit faster and cheaper radiation dosimetry techniques to be used. In both cases the use of much smaller samples than hitherto possible will bring many new opportunities to archaeological and environmental age measurements.

Age of the Olby–Laschamp geomagnetic polarity event

SEVERAL excursions or reversals of the Earth's magnetic field throughout the normal polarity Brunhes period which started 690,000 yr ago, have been reported recently; these were summarised by Verosub and Banerjee[1]. The first recent event to be reported was recognised by Bonhommet and Babkine[2] in lavas from the Chaîne des Puys (Massif Central, France) and was named the Olby–Laschamp magnetic event, but no precise date for this event has yet been obtained. An upper limit of 20,000 yr was suggested by K–Ar data[3] and has led to attributing to this event several recently discovered young magnetic events[4]. However, subsequent thermoluminescence and K–Ar data[5,6] indicate ages older than 30,000 yr. To clarify these age relationships I report here my dating of the Olby flow by the ^{230}Th/^{238}U radioactive disequilibrium method.

Table 1 U and Th concentrations and (^{230}Th/^{232}Th), (^{238}U/^{232}Th) activity ratios in Olby minerals

Minerals	^{238}U (p.p m.)	^{232}Th (p.p.m.)	$\frac{^{232}Th}{^{238}U}$	$\left(\frac{^{238}U}{^{232}Th}\right)$	$\left(\frac{^{230}Th}{^{232}Th}\right)$
Total rock TR	2.07	8.36	4.03	0.744	0 780 ±0.010
Pyroxene Px.	0 492	1.97	4.00	0 750	0 791 ±0 019
Plagioclase Pl.	0 523	2 29	4.38	0.685	0.783 ±0.018
Magnetite Mt1 80–23 μm	0 951	2.93	3.08	0 970	0.864 ±0.017
Magnetite Mt2 23–7 μm	1.52	4.01	2.63	1.142	0.904 ±0.017

The ^{230}Th/^{238}U method is well adapted to dating volcanic rocks younger than about 250,000 yr. It was successfully used in obtaining the ages of samples of the Irazu volcano (Costa Rica)[7] and of Etna (Sicily)[8]. The method is based on the following chronological equation:

$$\left(\frac{^{230}\mathrm{Th}}{^{232}\mathrm{Th}}\right)=\left(\frac{^{238}\mathrm{U}}{^{232}\mathrm{Th}}\right)(1-e^{-\lambda t})+\left(\frac{^{230}\mathrm{Th}}{^{232}\mathrm{Th}}\right)_0 e^{-\lambda t}$$

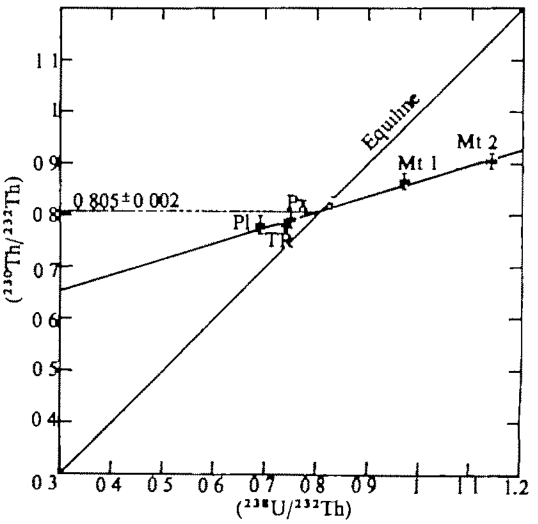
where the ratios are expressed in activity; λ is the ^{230}Th decay constant and ^{232}Th, considered as a stable isotope, is taken as a reference. The equation describes the return towards equilibrium between ^{238}U and ^{230}Th which has a characteristic period $T_{1/2}=75,200$ yr.

Minerals of a volcanic rock crystallise from a magma with different (^{238}U/^{232}Th) ratios due to chemical fractionation between U and Th, but with the same (^{230}Th/^{232}Th)$_0$ initial ratio if isotopic homogeneity is maintained. After a time t has elapsed their (^{230}Th/^{232}Th), (^{238}U/^{232}Th) define a line with slope $(1-e^{-\lambda t})$ from which the crystallisation age may be obtained[9]. The (^{230}Th/^{232}Th)$_0$ initial ratio is given by the intersection between the isochron and the principal bissectrix which is the position of the isochron when equilibrium is reestablished.

Details of the method and the analytical techniques are given elsewhere[7]. U and Th are measured by isotopic dilution and mass spectrometry. Errors in the (^{238}U/^{232}Th) ratios are estimated at 1%. Errors in the (^{230}Th/^{232}Th) ratios arise from counting statistics in α spectrometry measurements (1_σ).

The sample studied is a K-hawaiite with olivine, clinopyroxene, plagioclase and titanomagnetite phenocrysts, from the inversely magnetised flow of Olby[2]. The analyses were carried out on the total rock, clinopyroxene, plagioclase and two fractions of titanomagnetite of different grain size. The analytical results are reported in Table 1 and on Fig. 1. Least-square fitting of the data yield an age of 39,000 ± 6,000 yr and a (^{230}Th/^{232}Th)$_0$

Fig. 1 Internal isochron of the Olby sample, $t=39,000\pm6,000$ yr



0028–0836/78/0276—0257$01 00

initial ratio of 0.805±0.002. Thermoluminescence dating of quartz pebbles of a palaeosol under the Olby flow yield an age of 41,000±4,000 yr (ref. 10 and G. Valladas personal communication) which agrees well with my data.

Even though the duration of the Olby magnetic event is not known, most of the events found in the period 0–20,000 yr clearly cannot be attributed to the former. Denhan and Cox have shown that if the Olby–Laschamp event had affected the entire Earth's magnetic field it could not have happened between 13,300 and 30,400 yr, or lasted less than 1,700 yr. Other magnetic field disturbances known in the period 30,000–50,000 yr are the Lake Mungo event[12] which lasted from 28,000 to at least 31,000 yr, the Lake Biwa excursion[13] dated by extrapolation at 49,000 yr, an excursion the age of which is estimated at 40,000 yr in sediments from the Indian Ocean[14], and, possibly, an event recently discovered in Iceland (the Maelifell event)[15] which is not dated accurately yet. It is difficult to relate the latter events to the Olby–Laschamp one. If, however, the Lake Mungo and Olby–Laschamp disturbances represent the same event[15] this must have lasted several thousands of years (11,000±6,000 yr). Correlation between young magnetic disturbances, whether local or global, and their interpretation must await accurate dating.

I thank G. Poupeau who supplied the Olby sample, J. P. Pozzi for helpful discussion, and M. Semet for the English translation of the manuscript.

Phosphatic nodule beds in Victoria and the late Miocene–Pliocene eustatic event

CONTINENTAL evidence of the late Miocene expansion of the Antarctic ice cap and eustatic fall of sea level is still scarce. Here, phosphatic nodule beds in Victoria, Australia and other parts of the world are correlated with these events and with each other. Sedimentological and palaeontological evidence associates the Victorian beds with the late Miocene regressive phase and not with the succeeding early Pliocene phase of deposition. A fauna including whalebone, crabs and the nautiloid *Aturia*, accompanies the phosphatic nodules. The unusual abundance of phosphatic nodule deposits in the late Miocene is attributed to the contemporaneous evaporation, in the Mediterranean, of phosphate-deficient surface water derived from the North Atlantic, which created an enrichment in phosphate in the world ocean, of which the oversaturation surplus was precipitated. A further association of the phosphatic nodule beds with areas of upwelling is postulated to account for their discontinuous occurrence.

Deep-sea evidence indicates that in the late Miocene, the Antarctic ice cap formed and grew to a larger size than the present one, possibly including an extensive partly floating and partly grounded ice shelf[1,2]. Its growth is thought to have caused a eustatic fall in the sea level to at least 55 m below that at present[1]. The late Miocene was the time of maximum regression[1,3] and other events occurring in the higher southern latitudes, including the development of thermohaline circulation, the Antarctic circum-polar current[3], a thermally uniform water mass and the Antarctic Convergence[1,4], all thought to have migrated northwards at the time of maximum glaciation. In the Northern Hemisphere adjacent to the British Isles, a submerged marine terrace indicating erosion by a low sea level in the Miocene has been reported[5,6].

At Hamilton in western Victoria[7], a bed of calcareous clay containing phosphatic nodules rests unconformably on limestone and clay of early and middle Miocene age and contains abundant *remanié* foraminifera from both formations. At Minhamite, also in western Victoria[7], nodules are distributed through sediment of similar type for up to 40 cm above the unconformity, but here the basement and the foraminifera derived from it are of middle Miocene age only. The rich foraminiferal and molluscan faunas at these localities establish the correlation of the beds above the unconformity with the Jemmys Point Formation in Gippsland, the stratotype of the Kalimnan Stage (early Pliocene). *Aturia coxi*, a species known elsewhere from the late Miocene, has been recognised in the nodule bed at Minhamite[8].

At several localities in the Geelong district[9,10], phosphatic nodules occur on or immediately above an erosion surface which truncates marine sediments of early and middle Miocene age. Here they will be considered collectively. The sediment enclosing and overlying the nodules is a fine clay sand, containing a sparse, poorly preserved fauna of Kalimnan age. The Geelong area, alone of all the nodule bed localities considered here, lacks an abundant marine fauna in the formation above the unconformity. Fossil crabs occur frequently in the nodules themselves[10,11].

At Beaumaris, near Melbourne, a phosphatic nodule bed rests unconformably on middle Miocene clay and limestone and is overlain by 6 m of marine calcareous siltstones, above which another lithological and formational change occurs[7,12]. As at Hamilton, the beds immediately above the basal unconformity contain *remanié* foraminifera of both early and middle Miocene age and also *remanié* megafossils[13]. Specimens of *Aturia coxi*, whose matrix suggests that they occur in the interval 0–40 cm above the unconformity, suggest that these lowermost beds are of late Miocene age[8]. Bivalve and gastropod faunas obtained mainly from the beds 0.4–6 m above the unconformity have been shown to have closest affinities with faunas from Kalimnan (early Pliocene) strata and not with those of Miocene age[14,15].

The recent discovery of a phosphatic nodule bed immediately below the Jemmys Point Formation in the Lake Tyers–Lakes Entrance area of Gippsland extends the known nodule bed occurrences a further 330 km eastwards and shows that the nodule bed horizon underlies the Kalimnan stratotype[16]. *Globorotalia puncticulata* occurs almost immediately above the nodule bed in this area. Although this species has been reported from the late Messinian in the Mediterranean area and elsewhere[17], pre-Pliocene records are questionable[18] and the species is not known below the Pliocene in New Zealand[18,19].

One concludes that these Victorian occurrences of the unconformable nodule bed represent an eroded sea floor at the time of the lowest retreat of sea level during the late Miocene regression and is the surface over the rising sea transgressed during the latest Miocene or earliest Pliocene. If the extinction of *Aturia* is truly a Miocene event and the erosion surface represents the lowest still-stand, this apparently occurred slightly before the end of the Miocene.

0028-0836/78/0276—0258$01 00

At each of the Victorian nodule bed localities referred to here, except Geelong, cetacean vertebrae, ribs, ear bones, teeth and other bone fragments occur more commonly than at any other locality in the Tertiary of Victoria. Where the unconformity below the nodule bed has eroded early Miocene deposits, sharks' teeth also occur in the nodule beds with moderate frequency. Chiu[20] has reported a bed of frequently occurring whalebones, together with sharks' teeth and crabs in Taiwan at a level stated to be exactly on the Miocene–Pliocene boundary. Whether the abundance of whalebone at this time in Victoria, Taiwan and off southern California[21] (see below) is coincidental or indicates a peak in the abundance of whales at this time, is uncertain. Diastems at other levels in the Tertiary of Victoria do not concentrate whalebone.

Note that other well-known phosphorite occurrences, those on the South African continental shelf[22,23]; Chatham Rise[24,25] and Campbell Plateau[26] (east and south of New Zealand respectively); the phosphatic siderite deposits on the eastern Australian continental shelf[27] and those on the continental borderland of southern California[21,28] have also been attributed to a process of 'phosphatisation of late Miocene sediments' (*auct.*). Important associates of the nodules at the off-shore localities of South Africa are *Aturia* sp. and whalebone[22]; of southern California, whale and other marine mammal bones[21] and on the continental shelf of eastern Australia, crabs occur in the nodules as they do in the Geelong district.

The formation of the nodules in the Geelong district was considered by Coulson[9] to have been followed by a time of complete emergence from the sea, yet before deposition of the Kalimnan sands. Although Bowler[10] did not support complete emergence, he agreed that the nodules formed entirely during the regressive phase. The nodules of Chatham Rise are also thought to have been completely emerged after their formation[25] and as the present water depth is about 500 m, it seems unlikely that this occurred as recently as the Pleistocene. Dating of the nodule beds at Beaumaris and Minhamite as late Miocene by the presence of *Aturia coxi*[8], assigns them to the regressive phase and not to the early Pliocene transgressive phase. Evidence from other sources also dates the regression as late Miocene[29,30].

In South Australia, extending 300 km westwards of Hamilton, there are thin Pliocene deposits, usually resting disconformably or unconformably on older Tertiary or even pre-Tertiary rocks[31,32]. Some of them are dated as post-early Pliocene, but collectively they represent the deposits of a transgressive phase suggestive of a eustatic rise in sea level and their faunas contain many genera of foraminifera and molluscs restricted to considerably lower latitudes at present[15]. The Wright Valley in Antarctica was glacially eroded and vacated by the ice before 4.2 Myr BP and subsequently invaded by the sea during the Pliocene[33]. These observations are in accord with the raised southern ocean temperatures estimated for the early Pliocene[34] and apparently accompanying a eustatic rise in sea level.

A temporary northwards migration of the Antarctic convergence during the late Miocene glacial period could result in upwelling of Antarctic bottom water and consequent phosphate deposition on the Australian southern and eastern continental shelves, the Aghulas Bank, the Campbell Plateau and Chatham Rise. There seems little doubt that the upwelling of deep ocean water and phosphate deposition are closely associated[35].

In the Northern Hemisphere, circumstances which led to the formation of the Messinian evaporite deposits in the Mediterranean Basin[36,37] provide a possible mechanism for increasing the amount of phosphate available for precipitation from the world ocean at that time. These evaporites formed from seawater entering the Mediterranean over shallow sills[36] and it has been estimated that they represent 6% of the total dissolved salts in the world ocean at that time[38]. The supply of this evaporite material would have been drawn selectively from North Atlantic surface water, in which the phosphate content is less than in bottom and intermediate water in the Atlantic and other oceans[39]. The result would be a net increase in dissolved phosphate in deep water in all oceans, thus creating a situation in which increased phosphate precipitation in areas of upwelling could be expected to have occurred in the late Miocene.

Confirmation of ^{137}Cs dating by algal stratigraphy in Rostherne Mere

THE deep sediments of Rostherne Mere, Cheshire (National Grid Reference SJ 745843) offer a promising situation in which to study the relationship between biological stratification and radionuclide dating in the absence of gross bioturbation. The mere is small (46.5 hectare), but relatively deep (30 m maximum), and is reported to be largely devoid of benthic fauna in the persistently deoxygenated deep sediments[1]. The sediments of Rostherne Mere contain the remains of a great variety of algae, in addition to diatoms. The preservation of non-siliceous algae is uncommon, although found in the sapropel deposits of the USSR[2]. In Rostherne the empty spores of *Ceratium hirundinella* O.F. Mull., *Anabaena* species and *Aphanizomenon flos-aquae* (L) Ralfs are recognisable, as are colonies of *Microcystis* species and cells of *Staurastrum* species. The phytoplankton of Rostherne Mere has been recorded at intervals since 1912 (refs 3–5) and sampled more frequently from 1962 (refs 6–8). The recent records (Table 1) show fluctuations in summer dominance, mainly between *Ceratium hirundinella* and *Microcystis aeruginosa* Kütz. emend., but blue–green algae

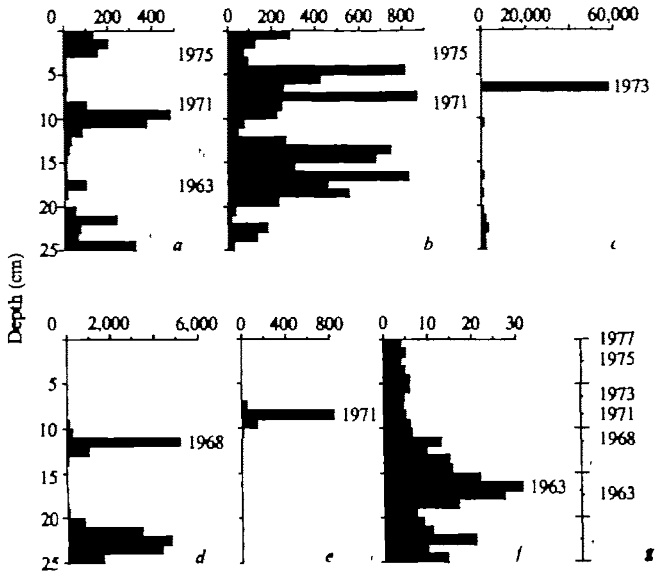
Sources: 1962–63, ref. 6; 1964–66, ref 7; 1967–77, ref. 8. No data available for 1976, 74, 70 and 69.

have become increasingly dominant[9]. These changes, combined with occasional maxima of the diatoms *Melosira granulata* (Ehr.) Ralfs, *Cyclotella pseudostelligera* Hust. and *Stephanodiscus astraea* (Ehr.) Grun., can be correlated with algal assemblages in the sediments and permit these to be accurately dated. We now report that such algal remains from the lake sediment have been used to establish a detailed chronology which is shown to confirm the ^{137}Cs dating method.

Three 1-m cores[10] extracted from the deepest area of the mere were examined throughout for algal remains, and all showed the same well-defined stratigraphy. The algal species which are most numerous in the upper 25 cm of the cores are shown in Fig. 1 (*a–e*), and the patterns found reflect the changes in plankton dominance. Thus an 'algal chronology' can be constructed by comparing the sediment biostratigraphy with the observed and dated records of the plankton (Fig. 1*g*). The fact that the remains of many different algae are recognisable in the bottom deposits of Rostherne Mere permits a detailed correlation. Hence, the *Ceratium*-dominant years of 1963, 1971 and 1975 are allocated to the 17-cm, 9-cm and 3-cm horizons, respectively (Fig. 1 *e,d*).

Fig. 1 Algal and caesium stratigraphy. *a*, *Ceratium hirundinella* spores; *b*, *Microcystis* spp. colonies, *c*, *Stephanodiscus astraea* cells; *d*, *Melosira granulata* cells; *e*, *Cyclotella pseudostelligera* cells; *f*, caesium-137 pCi per section; *g*, algal chronology. *a–c*, Numbers expressed per 5 µl of fresh sediment, *d,e*, per 0.1 µl of fresh sediment. A 1-cm thick section of a core contains 29 ml of fresh sediment.



Two of the cores were dated by the distribution pattern of ^{137}Cs (refs 11,12). Sections 1 cm thick were dried and analysed by γ-ray spectrometry[13] using a germanium (lithium) detector. The position of greatest concentration of ^{137}Cs, corresponding to 1963, occurred at a depth of ~17 cm in both cores and this demonstrates consistency between the cores and also agrees with the chronology established from the algal record. The ^{137}Cs profile from one of the cores is shown in Fig. 1 *f*. An earlier core dated by the ^{137}Cs method and reported by Gaskell and Eglinton[14] showed about half the accumulation rate of the present cores. Such variations in accumulation rate at different locations are not unusual and have been discussed elsewhere[15].

The deep sediments of Rostherne Mere have proved to be an ideal environment for the preservation of a variety of non-siliceous algae. Much of the sediment volume is derived from the high algal productivity of the mere, and these autochthonous deposits give a detailed insight into past phytoplankton communities. Also, the high rate of sediment accumulation (~1 cm yr^{-1}) ensures that a 1-cm slice provides adequate resolution of annual increments. The apparent absence of large benthic animals ensures that the ordered structure of the stratigraphic column is not likely to be grossly disrupted by bioturbation, and this is confirmed by the identical position of the ^{137}Cs peak in both the cores analysed.

Such conditions will not necessarily apply in other lakes, where there may be greater diffusion in the sediment column or more significant contribution from the catchment. Rostherne Mere is unusual because of the high autochthonous contribution to the sediment and small inflow of fine particulate allochthonous material. This is the first site in Great Britain at which independent evidence has been found for the validity of the dating of lake sediments provided by ^{137}Cs.

We thank Drs J. W. G. Lund, W. Pennington and C. S. Reynolds for advice and discussion, Miss E. M. R. Fisher who performed the ^{137}Cs analyses, Mr. P. V. Allen for technical assistance, the Nature Conservancy Council for permission to work on Rostherne Mere, and the warden, Mr T. Wall, for his help. D.L. is in receipt of a NERC Studentship.

Temporal decline in attractiveness of honeybee queen tracks

A BODY or surface (such as that of a worker bee or a cage) that has been in contact with a honeybee queen becomes attractive to worker bees[1–3] due to contamination with queen pheromones[3,4]. Little information is available about the durability of those pheromones, apart from Butler's report that 30 min after removal of the queen a cage becomes less attractive to the workers, and loses its attractiveness entirely after a further hour[1]. I report here experimental evidence of a temporal decline in the attractiveness of tracks left on a waxed surface by a queen.

I monitored the accumulation of worker bees on a wire-gause cage which contained a queen[4,5] or had been marked with her tracks on the inner surface. To achieve experimental conditions as near as possible to those inside a hive, the accumulation of bees was determined by weighing the cage with them on it. The cage was suspended from one of the arms of a balance and was let down, through a hole in the ceiling of the hive, over the brood chamber of the test colony. It was possible to put the queen into the cage and remove her from it without taking the cage from the hole. The cage was left over the brood chamber during the test, and the worker bees had easy access to it.

The cages used were covered with wax, and before the experiments they were kept in the hive of the test colony, which had a mated laying queen.

The bees that gathered on the cage containing a live mated queen were weighed. Then the queen was removed and weighing was repeated at 1-min intervals. The data obtained were used to give the relative attractiveness of queen tracks as a function of time (Fig. 1): it demonstrates a clear decline.

My results show that queen tracks can contain at least one pheromone that loses its effectiveness quite quickly, whereas the best known pure pheromone (9-oxodecenoic acid) has been reported[1] to remain detectably active in very small quantities for 7 yr.

The decline of attractiveness may occur either through volatilisation of the pheromone or in some other way. If queen tracks are assumed to form a thin film over a surface, the pheromone molecules in the film being dispersed far enough one from another (and consequently having an equal chance to leave the surface), the density of the molecules in the air near the surface (due to volatilisation) can be shown[6] to change by the factor $\exp(-t/\tau)$ where t is time and τ is a positive parameter independent of t. The attractiveness of queen tracks can be expected to change in the same way. As Fig. 1 shows, the experimental data agree with this. Therefore the temporal change in attractiveness of queen tracks to worker bees is determined by τ ($27.9 \leq \tau \leq 29.2$ min for 95% confidence level). The halflife is 19.3–20.3 min.

Some evidence for a similar rate of loss of attractiveness of queen tracks is provided by Velthuis's observations of interactions between a group of queenless worker bees and "substitute queens" (workers bearing queen pheromones on their bodies). The attractiveness of the substitute queens lasted 5–45 min, the mean duration being 15 min (ref. 3).

Thus queen tracks are attractive to workers (and therefore are perceived by them) for sufficient time to have a possible influence on the behaviour of the workers and the state of the colony. On the other hand, the tracks lose their attractiveness (and cease to be perceived) sufficiently quickly to account for the rapid onset of queenless behaviour in a colony deprived of its queen.

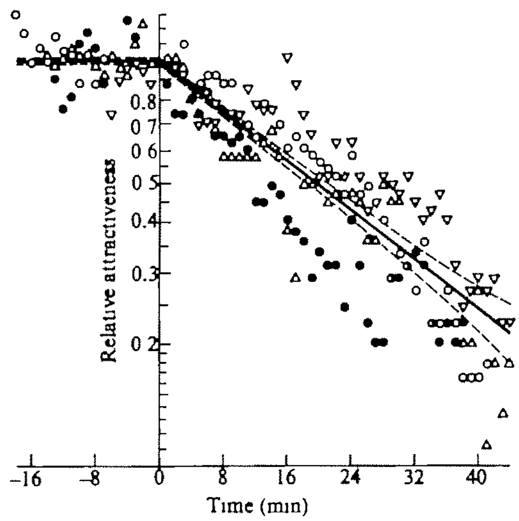

Fig. 1 Relative attractiveness to worker bees of a caged live mated queen (time < 0) and queen tracks left on the inner surface of the cage (time > 0) The different symbols correspond to data collected in four separate tests.

This work was carried out at the Institute of Zoology and Parasitology, Lithuanian Academy of Sciences. I thank Dr P.-H. Vaitkevičius for helpful comments, Dr Aldona Katkauskaitė for help with data analysis and Mr R. Matulis for revising the English text.

The living coelacanth *Latimeria chalumnae* does not have a cloaca

POSSESSION of a cloaca is presumed to be a primitive vertebrate character that has been lost independently four times—in lampreys, chimaeras, actinopterygians and eutherian mammals—as the adult morphology of the urinary-genital-rectal openings is different in each group. Hagfishes, sharks, lungfishes, amphibians, reptiles, birds, monotremes, marsupials and *Aplodontia rufa* all possess a cloaca[1]. Millot and Anthony[2] stated that the male *Latimeria* has a true cloaca whereas the female has a rectal opening separate from a common urinary-genital opening. We report here evidence that neither male nor female *Latimeria chalumnae* has a cloaca.

Male and female specimens of *Latimeria* were dissected to follow the digestive, urinary and reproductive tracts to their posterior openings. A plastic strip was inserted into the urethral

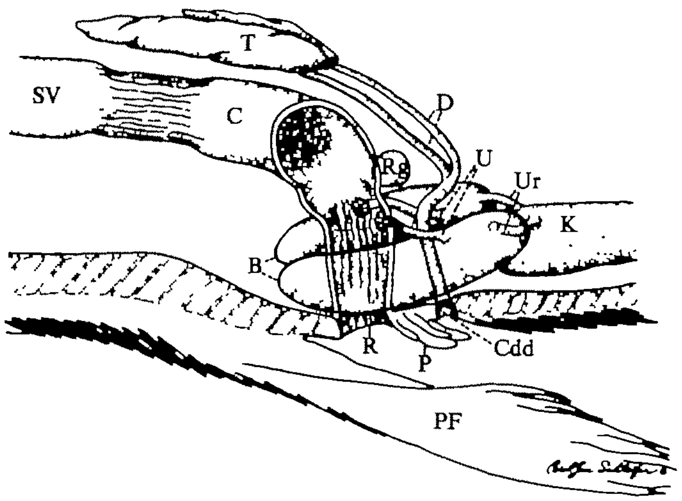

Fig. 1 Male rectal-urinary-genital anatomy of *Latimeria chalumnae*, lateral views, anterior to the left. Based on: AMNH 36941 (American Museum of Natural History) coelacanth 25 in the list of captured specimens[3], 130 cm in total length, captured off Anjouan, Comoro Islands 10 October 1961, obtained from the Muséum National d'Histoire Naturelle, Paris; CAS 24862 (California Academy of Sciences) coelacanth 59, 122 cm in total length, captured off Itsoundzou, Grande Comore, Comoro Islands 1 January 1970; and LACM 6824-1 (Los Angeles County Museum of Natural History), 121 cm in total length, captured in the Comoro Islands in 1970 and not included in the list of coelacanth captures[3]. B, urinary bladder; C, colon; Cdd, common ductus deferens; D, ductus deferens; K, kidney; O, oviduct; P, papillary bodies; PF, pelvic fin, R, rectum; Rg, rectal gland; SV, spiral valve of the intestine; T, testis; U, urethra; Ur, ureter. (In using the above anatomical nomenclature we realise some would question the possibly implied homology between some of the osteichthyan and tetrapod structures. We do not necessarily imply such homology, but merely use the standard terms to name the structures.)

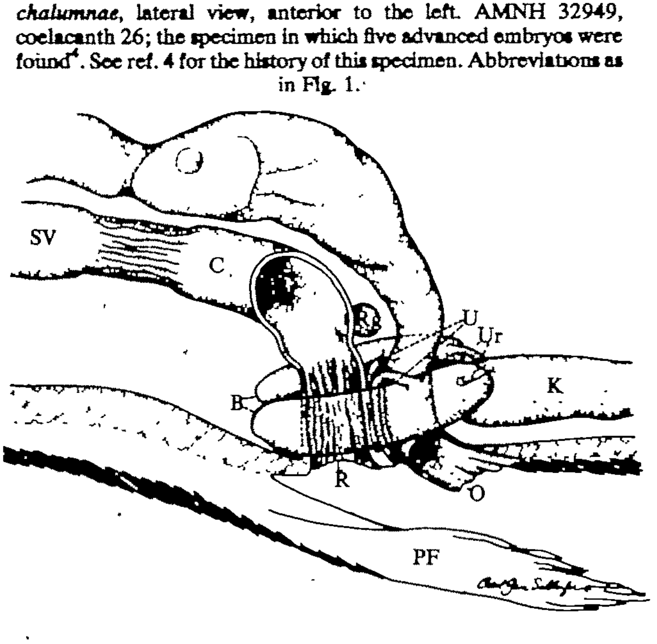
aperture in one of the urinary bladders and pushed through the urethra until it emerged from its distal opening. The other urethra in each specimen was slit open to follow the route of the urethra to the exterior. The oviduct of the female (AMNH 32949) had been opened previously, and was greatly enlarged due to the five advanced embryos it had contained. In the male (AMNH 36941), the left and right ducti deferentes were followed from the testes (the left testis was considerably larger than the right) to the point at which they anastomose, from whence a probe was passed down the common ductus deferens to its external opening. The lower colon and upper rectum were slit open in the male; the entire length of the lower digestive tract of the female had been opened previously.

Fig. 2 Female rectal-urinary-genital anatomy of *Latimeria chalumnae*, lateral view, anterior to the left. AMNH 32949, coelacanth 26; the specimen in which five advanced embryos were found[4]. See ref. 4 for the history of this specimen. Abbreviations as in Fig. 1.



In the male, the urethras descend from the right and left urinary bladder and empty into the posterior wall of the rectum. A series of papillae surround the urethral openings where they join the rectum. The right and left deferent ducts descend from their respective testes and fuse into a common ductus deferens. From the point of fusion, the common ductus deferens descends ventrally and opens externally (Fig. 1). Two additional male coelacanths (CAS 24862 and LACM 6824-1) also have the urethras opening high into the rectum without fusing with each other or with the two deferent ducts. In the female, the right and left urethras descend from the right and left urinary bladders and open directly to the outside on their respective antero-lateral sides of the oviduct. The oviduct itself opens directly to the exterior (Figs 2, 3).

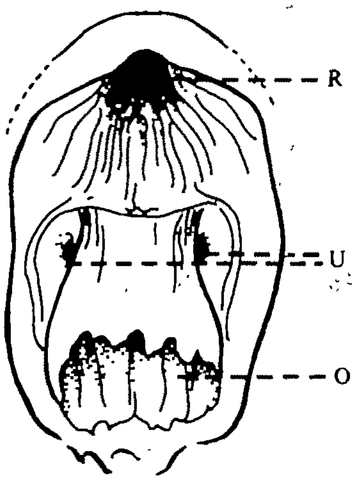


Fig. 3 Ventral view of rectal-urinary-genital openings of female *Latimeria chalumnae*, AMNH 32949. Anterior is to the top, abbreviations as in Fig. 1.

We conclude that neither male nor female *Latimeria* has a cloaca and that the sexes are dimorphic: in the male the urethras empty into the rectum whereas in the female they open directly to the exterior. The anatomy of these openings in the female *Latimeria* is identical with that in many actinopterygians. However, the apparently plesiomorph condition for actinopterygians occurs in *Acipenser*, *Lepisosteus* and *Amia*, namely a rectal opening separate from a common uro-genital opening[1]. This differs from the presumed plesiomorph condition for *Latimeria* which is maintained in the male as a common uro-rectal opening separate from the genital opening. We conclude that *Latimeria* exhibits another independent loss of the primitive cloaca.

Morphological variance and enzyme heterozygosity in the monarch butterfly

It was shown several decades ago that the reduction in genetic heterozygosity produced by inbreeding in domesticated plants and animals is accompanied by an increase in morphological variability[1,2]. While studies of laboratory populations and results of plant and animal breeding have been instrumental in identifying the relationship between genetic heterozygosity and morphological variability, such investigations often involved substantial changes in genetic heterozygosity, such as are produced when entire chromosomes are made homozygous. For this reason their relevance to the levels of heterozygosity in natural populations is unclear. Until recently attempts to examine this relationship in natural populations were hindered by the inability to routinely estimate levels of genetic heterozygosity in nature. However, determinations of genetic heterozygosity at specific enzyme-loci can now be made by electrophoresis. Recently Mitton[3] found that heterozygotes for a set of five enzyme-loci had reduced multivariate variances for a set of morphological characters when compared to homozygotes at the same loci in populations of the killifish, *Fundulus heteroclitus*. It is very important to determine the generality of this observation for other species populations. I have now examined the relationship between genetic heterozygosity, as identified by electrophoresis, and the variance of morphological characters in the monarch butterfly, *Danaus plexippus*. Study of six polymorphic enzyme-loci in the monarch shows that once again heterozygotes have smaller variances for morphological characters when compared to homozygotes at the same locus.

The data for this study were gathered from over 1,400 monarch butterflies collected in the eastern USA and Canada during the summers of 1974–75. The sample sites, dates of collection, sample sizes, and electrophoretic methods are given in ref. 4. Six polymorphic enzymes were examined; glucose phosphate isomerase(GPI), malate dehydrogenase(MDH), glutamate-oxaloacetate transaminase(GOT), mannose phosphate isomerase(MPI), phosphoglucomutase(PGM), and a TPN-dependent 'nothing' dehydrogenase(NDH). Electrophoretic variation at all six loci is inherited in a mendelian fashion, and it is known that the GPI, PGM and NDH loci are chromosomally unlinked. The chance of linkage between the other pair combinations is small.

Right forewing length and the diameter of the major forewing spot (divided by the length of the adjacent wing vein) were measured on each individual. These characters are normally distributed with a slight skew towards the smaller values. The correlation between characters is statistically nonsignificant ($r = 0.096$, $n = 54$). The characters are sexually dimorphic, and therefore males and females were treated separately in the analysis. There is very little geographic (sample) variation for either character; less than 2% of the total variance in either character can be attributed to between sample differences. Sample character variances are statistically homogeneous.

The association between genetic heterozygosity and morphological variability was examined by comparing the character variances of homozygotes and heterozygotes at each locus. Since there are two independent characters, six enzyme-loci, and both males and females to consider, this results in 24 statistical tests of the null hypothesis of no difference in character variances between homozygotes and heterozygotes. The results of those tests are given in Table 1. Because of the considerable differences in heterozygosity among the loci, and the smaller sample size of females, there is a substantial range of statistical power from test to test; the tests for GOT and MDH in females are the weakest.

The results show that homozygotes generally have larger variances for these morphological characters compared to heterozygotes at the same locus. The results are the strongest for character 2. Overall, 19 of the 24 comparisons show homozygotes with larger variances, and five tests are statistically significant at the 0.05 level. None of the exceptions approach statistical significance. The distribution of test probabilities is noticeably skewed; 14 of 24 tests have probabilities less than 0.20. The results clearly support the hypothesis that heterozygotes at these loci tend to be found near the centre of the morphological character distributions.

Table 1 Comparisons of morphological variances for enzyme homozygotes and heterozygotes in *Danaus plexippus*

GOT	0.028(374)	0.030(20)	0.93	0.631
MDH	0.029(366)	0.020(28)	1.45	0.110

Sample sizes are given in parentheses. F_s is the ratio homozygote s^2/heterozygote s^2. P is the probability associated with the one-tailed F test of the null hypothesis; σ^2homozygotes = σ^2heterozygotes. Forewing length variance is in mm^2, and the forewing spot variance is dimensionless. Significant values underlined.

It should be noted that some electrophoretic variants do not represent homogeneous allelic products, but instead are mixtures of different variants with similar electrophoretic appearance[5–8]. Consequently some heterozygotes will be misclassified as homozygotes, and this should tend to obscure the proposed association. The magnitude of this effect cannot be assessed in this study.

Problems certainly arise when assuming morphological variability to be a reasonable measure of developmental homeostasis. Morphological variability may predominantly reflect the segregation of additive and nonadditive genes rather than the expression of developmental instability. An association between enzyme heterozygosity and morphological variability could then be generated by electrophoretic variant alleles being in linkage disequilibrium with the genetic factors determining the morphological variance. It would be expected for electrophoretic heterozygotes to exhibit intermediate morphological values and smaller variances on the average. If this were the source of the observed association, then specific homozygous and heterozygous phenotypes should possess different mean values for the morphological characters. This was not the case. Of the 24 ANOVA tests performed to test for differences in

0028-0836/78/0276—0263$01 00

means between specific electrophoretic phenotypes, *none* were statistically significant. The ANOVA assumes equality of variances, a condition not satisfied here, however the test is robust to small deviations in homoscedasticity[9]. The outcome of these tests indicates that enzyme homozygosity affects the deviation from the morphological mean, and that the direction of that deviation does not depend on specific homozygous phenotypes.

The connection between genetic heterozygosity and developmental homeostasis led early investigators to propose that developmental buffering was enhanced by enzyme polymorphism along biochemical pathways[10-12], although few methods were available to assess levels of genic heterozygosity. The widespread use of electrophoresis in recent years and the discovery of extensive molecular polymorphism has prompted interest in the adaptive significance of enzyme polymorphism[13,14]. Surprisingly little attention has been paid to the potential role of this enzyme heterozygosity in developmental homeostasis.

The results presented here suggest that genetic heterozygosity and perhaps enzyme heterozygosity *per se* are associated with developmental homeostasis in natural populations. However, the observation also involves a serious paradox. As each monarch butterfly is potentially heterozygous for thousands of such loci, all contributing in a similar fashion, it seems unreasonable to expect to observe this effect for any random set of six loci. Over the entire genome each individual should have approximately the same average heterozygosity, and the specific contribution of any single locus should be obscured. It must, therefore, be assumed that either these particular six loci possess unexpectedly strong contributions, or that they serve as indices of overall genetic heterozygosity. There is no reason to attribute special effects to these enzymes, but homozygosity could be associated across many loci, either through inbreeding (inbred individuals will be concurrently homozygous for many loci), or through linkage disequilibrium of large blocks of loci. No evidence can be found for significant levels of inbreeding in the monarch population[4]. There is already ample evidence from several studies in *Drosophila* that electrophoretic variants can be in strong linkage disequilibrium with linked chromosomal inversions[15-19]. Unfortunately nothing is known about the plausibility of inversion polymorphism in Lepidoptera.

The results of this study are important because they help to generalise the observation that morphological variability and genetic heterozygosity are related in natural populations. While it is not clear what role enzyme polymorphism of the type identified by electrophoresis plays in this association, it is apparent that natural selection, by removing the morphologically extreme, will favor heterozygosity at several of these enzyme-loci[20,21].

I thank R. K. Koehn for encouragement. Financial support came from USPHS grant GM-21133 to R. K. Koehn and NSF grant B393000 to J. R. G. Turner. Travel funds were provided by a Theodore Roosevelt Memorial Grant.

Humans and apes are genetically very similar

MAN'S closest living relatives are the great apes—the African chimpanzee and gorilla, and the Asian orangutan. Humans (*Homo*) are classified in the family Hominidae; chimpanzees (*Pan*), gorillas (*Gorilla*) and orangutans (*Pongo*) are classified in the family Pongidae. The gibbons, or lesser Asian apes (genera *Hylobates* and *Symphalangus*), are classified in the family Hylobatidae. All three families of humans and apes are included in the superfamily Hominoidea. Linnaeus recognised the basic morphological similarities between humans and apes by placing them together in the order primates (Anthropomorpha), although in separate genera. He did not use any category of classification intermediate between 'genus' and 'order'. However, when the 'family' category was introduced, humans and apes were placed in separate families. The prevailing view of modern taxonomists has been expressed by Simpson[1]: "*Homo* is both anatomically and adaptively the most radically distinctive of all hominoids, divergent to a degree considered familial by all primatologists". With the methods of classical mendelian genetics it is impossible to make genetic comparisons between species which cannot be hybridised, as the presence of genes is ascertained by studying segregation in the progenies of crosses between individuals exhibiting different traits. However, advances in molecular biology have made possible comparisons between DNA sequences or, more often, between proteins from different organisms. If the proteins are identical in amino acid sequence, the genes coding for them are assumed to be identical. (This is not always true owing to the redundancy of the genetic code, but DNA nucleotide differences which change the encoded protein have greater evolutionary consequences than those which do not.) Many proteins from different organisms can be readily compared by means of gel electrophoresis. Although not all amino acid differences are detected by this method, it provides reasonably satisfactory estimates of the relative degree of genetic differentiation between closely related species. King and Wilson[2] studied electrophoretically 44 gene loci coding for proteins in humans and chimpanzees (*Pan troglodytes*), and found them to be about as similar as very closely related species of other organisms are to each other. We now report results confirming that finding and extend it to comparisons between humans and the other apes.

Using polyacrylamide and starch gel electrophoresis, we have studied 23 gene loci coding for blood proteins in humans (*Homo sapiens*), the two species of chimpanzee (*P. troglodytes* and the pygmy chimpanzee, *P. paniscus*), the gorilla (*Gorilla gorilla*), the Sumatran and the Bornean orangutans (*Pongo pygmaeus abelii* and *P. p. pygmaeus*), and three species of gibbons (*Hylobates lar*, *H. concolor* and *Symphalangus syndactylus*. Table 1 gives the genetic identity and the genetic distance for the comparisons between humans and each of these organisms. The genetic identity, I, may vary between 0 (complete genetic differentiation at every locus) and 1 (complete identity at every locus). The genetic distance, calculated as $D = -\log_e I$, may vary between 0 and ∞, and estimates the number of electrophoretically detectable allelic substitutions that have occurred in the evolution of two species since their last common ancestor[3]. Table 1 also gives the number of individuals studied for each ape species. The 10 gorillas are unrelated wild-born animals; all other animals are either wild-born or unrelated to each other.

Humans are genetically about equally differentiated from all the great apes; on average, about 35.4 electrophoretically

Averages†				
Great apes (1–5)	23	48	0.702 ± 0.009	0.354 ± 0.013
Lesser apes (6–8)	21	7	0.417 ± 0.045	0.887 ± 0.112
All apes (1–8)	21	55	0.595 ± 0.055	0.554 ± 0.105

* The proteins studied were adenosine deaminase, adenylate kinase, catalase, fumarase, glucose-6-phosphate dehydrogenase, glutamate oxaloacetate transaminase, haemoglobin $\alpha\beta$, isocitrate dehydrogenase, lactate dehydrogenase, malate dehydrogenase, NADH-diaphorase, phosphoglucoisomerase, phosphoglucomutase, 6-phosphogluconate dehydrogenase (red-cell proteins), albumin, alkaline phosphatase, ceruloplasmin, esterase, haptoglobin, leucine aminopeptidase (plasma proteins). The following are omitted: adenosine deaminase in the gorilla and the three lesser apes, catalase in the three lesser apes and fumarase in *P. troglodytes*.

† Arithmetic means with their standard errors.

detectable allelic substitutions have occurred for every 100 gene loci in the separate evolutions of man and each of the apes. As expected, the genetic differentiation is larger between humans and the lesser apes, but even here the degree of genetic differentiation is relatively small; on average, there have been about 88.7 allelic substitutions per 100 loci.

The significance of these results becomes apparent when they are compared with electrophoretic data obtained in other animal groups. The average genetic distances (calculated from published data, mostly in ref. 4) between pairs of closely related species are as follows: *Drosophila* flies, $D = 0.827$ (8 species); fish, $D = 0.622$ (4 species); salamanders, $D = 0.296$ (3 species); lizards, $D = 0.828$ (2 species); rodents, $D = 0.359$ (7 species). Although estimates of D are subject to large potential errors (typically, the standard error for a comparison based on 20–30 gene loci may be nearly half as large as the estimate), we may conclude that humans and apes (particularly the great apes) are genetically about as different from each other as closely related species of the same genus in other groups of organisms.

The genetic distance between man and *P. troglodytes* obtained by King and Wilson was $D = 0.62$, about 60% greater than the value obtained by us ($D = 0.386$). Although the two estimates are not significantly different from each other, it is worthwhile to examine the basis for such difference. King and Wilson studied 44 gene loci, whereas we have surveyed only 22 loci in these two species, 18 of which were included in their study. The difference in the two estimates of genetic distance could be accounted for, at least in part, if on average the loci surveyed by them but not by us were more different than the rest, or if the loci surveyed by us but not by them were less different than the rest. This is not, however, the case: when only the loci common to both studies are included in the estimation, the values of D remain approximately as different as for the complete samples. Therefore, the main reason for the higher estimate obtained by King and Wilson is that different electrophoretic methods were used in the two studies, and their methods must have allowed them to detect a greater number of differences.

Three observations should be made. First, the electrophoretic methods used with non-primate species are more similar to our methods than to those of King and Wilson (in fact, many of the studies have been carried out in our own laboratory); thus, our D value is more appropriately used when comparing the genetic differentiation between man and apes with that between other organisms. Second, the use of the D value obtained by King and Wilson does not alter the qualitative conclusion reached that man is genetically no more different from the great apes than are closely related (congeneric) species in other animal groups from each other. (And less different than genera of the same family are in such organisms; for these, we have obtained the following D values: fish, 1.772; salamanders, 0.828; rodents, 1.833.) Third, electrophoretic methods do not detect all amino acid differences between proteins and thus underestimate genetic differentiation; however, this bias should be similar in primates and in other animals and therefore would not affect the validity of the conclusion reached.

The results presented here lead to a paradox. We perceive ourselves as being considerably different in morphology and behaviour from the apes, and this can hardly be exclusively attributed to the fact that humans more readily notice differences involving themselves (indeed, see the statement by Simpson[1] quoted above). However, we have obtained estimates of genetic differentiation between humans and the great apes no greater than, say, those observed between morphologically indistinguishable (sibling) species of *Drosophila* flies. One possible resolution of this paradox is to assume that the estimates are biased; there are thousands of structural gene loci and the few surveyed might not represent a random sample of the whole genome. This is indeed possible but there is no reason to suspect that the sample is biased. Another, more interesting alternative, has been suggested by King and Wilson[2] as well as by others[5–7]. It may be that morphological and behavioural evolution involves primarily changes in gene regulation rather than changes in structural gene loci (that is, those coding for proteins). If this is so, substantial differences in genetic regulation would exist between humans and apes. We favour this alternative. Although this hypothesis is not supported by any direct evidence, it is favoured by some indirect evidence[1] as well as by the demonstration in *Drosophila* that adaptation may occur through changes in regulatory rather than in structural genes[8].

Totipotent cells of parthenogenetic origin in a chimaeric mouse

IN strain LT/Sv mice, eggs often begin to develop parthenogenetically in the ovary after the first meiotic division[1-3]. They undergo apparently normal cleavage and blastocyst formation, but at the egg cylinder stage they become disorganised and form teratomas. They persist as tumours composed of many kinds of tissue, indicating that cells of parthenogenetic origin are viable. Spontaneous parthenogenesis is also common in ovulated strain LT eggs. They cleave, form blastocysts and implant in the uterus, but die shortly afterwards, in the same way that embryos derived from experimentally induced parthenogenesis die early[4-7]. However, parthenogenetic cells have been 'rescued' by removing embryos from the oviducts of virgin females and grafting them to extrauterine sites such as testis[1] and kidney[8]. Those embryos become disorganised and can survive as teratomas composed of many kinds of viable tissues. Why, then, do cells of parthenogenetic origin fail to survive *in utero*? To investigate this problem we are using chimaeras derived from aggregates of eight-cell parthenogenetic and normal embryos[2], transferred to the uteri of pseudopregnant females. We report here that early embryonic parthenogenetic cells are totipotent. They can give rise to fully functional ova which, when fertilised by sperm, develop into normal individuals.

Parthenogenetic four- and eight-cell embryos of the pigmented strains LT/Sv and LTXBJ and their F_1 hybrids, and embryos derived from normally fertilised eggs of albino strain 129/Sv and (129 × A/He)F_1, were flushed from the oviducts of superovulated females. After removal of the zona pellucida with Pronase, one normal and two parthenogenetic embryos were aggregated in Whitten's[9] medium in an atmosphere of 5% CO_2, 5% O_2 and 90% N_2 at 37 °C. The aggregated 'triplets' were transferred in groups of about 10 to the uteri of pseudopregnant (SJL × C57BL/10)F_1 females; 456 aggregates were transferred to the uteri of 47 females. Twenty-four offspring were produced and six were identified as chimaeras by their partially pigmented coats and irises (Table 1). Four male and two female parthenote ↔ normal chimaeras were produced. All were mated with strain 129 albinos. The four males sired 285 offspring, all albinos. Chimaera no. 19 (129 × A/He)F_1 ↔ (LT × LT × BJ)F_1 produced 33 albino offspring. Chimaera no. 53 (129 ↔ LT) produced five litters of 29 albino offspring. Her sixth and last litter contained two albino and two (one male and one female) pigmented offspring (Fig. 1). The pigmented offspring could only have been derived from ova of parthenogenetic origin (LT) fertilised by normal albino (129) sperm.

We were able to identify the parthenogenetic origin (LT) of the ova of chimaera no. 53 by a genetic marker other than *C*, which determined the pigmented coats of her offspring. Strain LT is Hbb^s/Hbb^s, which produces an electrophoretically single haemoglobin, and strain 129 is Hbb^d/Hbb^d, which produces a diffuse electrophoretic pattern[10]. Cellulose acetate electrophoresis of mouse haemoglobins modified with the disulphide reagent cystamine permits rapid, unequivocal discrimination of all combinations of the co-dominant mouse haemoglobin 'single' (Hbb^s) and 'diffuse (Hbb^d) alleles[11]. Examination of the blood of the two pigmented offspring revealed that they were heterozygous Hbb^s/Hbb^d. The Hbb^s allele could only have been derived from ova of parthenogenetic LT origin.

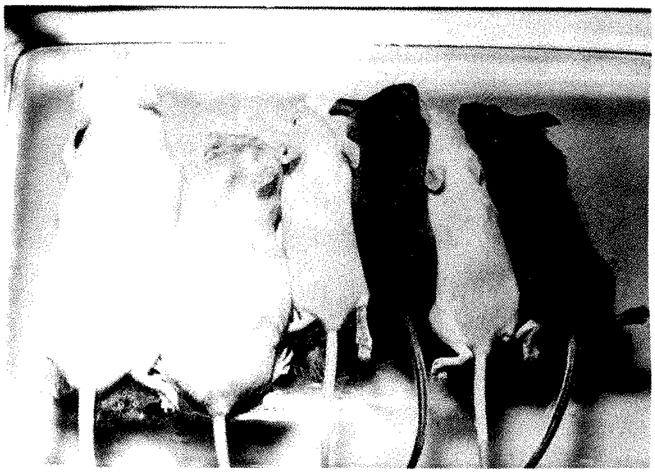

Fig. 1 An albino male (left) was mated to a chimaeric female (second from left) derived by aggregating normal and parthenogenetic 8-cell embryos. This mating produced a litter with two albino (derived from normal eggs) and two pigmented (derived from eggs of parthenogenetic origin) young.

Two of the chimaeric neonates were about half the size of their normal littermates. This suggested the possibility that in aggregates with parthenogenetic cells there is extensive cell death. To increase the possibility of having more parthenogenetic cells per embryo, parthenogenetic embryos were aggregated with other parthenogenetic embryos and transferred to the uteri of pseudopregnant females; 55 aggregates were transferred and five were recovered after implantation.

One female received nine aggregates of four parthenogenetic four-to-eight-cell embryos. Two abnormal embryos implanted; one had only a small amount of ectoderm undergoing necrosis and abnormally arranged parietal endodermal cells. The other was at the 6-d stage. It was larger than normal but the ectoderm was irregularly arranged.

Another female received 10 aggregates of three parthenogenetic embryos. There were three implantations; two were at the 5-d stage, with proamniotic cavities lined by dying ectodermal cells; the third was more advanced, but very abnormal. It had a primitive streak, chaotically arranged mesodermal cells,

Table 1 Production of chimaeras by aggregating normal and parthenogenetic embryos

129/Sv	(LT/Sv × LTXBJ)F_1	96	10	2	0
				4	3 (341, 42, 43)
129/Sv	LTXBJ	7	1	0	0
(129 × A/He)F_1	(LT/Sv × LTXBJ)F_1	80	9	2	1 (137)
				4	1 (19)
				3	0
		456	47	24	6

* Numbers in parentheses refer to designated chimaera no.

0028–0836/78/0276—0266$01.00

and an abnormal amnion, allantois and chorion. Although spontaneous parthenotes rarely develop to such an advanced stage, it is not certain that the advanced development was due to the increased number of cells produced by the aggregation of three embryos. These results suggest that increasing the number of cells in a parthenogenetic embryo will prolong its survival *in utero*.

Even though pure parthenogenetic embryos will not survive *in utero*, these results demonstrate that their cells are capable of participating in normal development when associated with normal cells. Furthermore, the production of offspring with the *C* and *Hbb*^{s} alleles from an aggregation chimaera between a parthenogenetic *C/C Hbb*^{s}*/Hbb*^{s} and a normal *c/c Hbb*^{d}*/Hbb*^{d} embryo demonstrates that fully functional totipotent ova of parthenogenetic origin were produced.

I thank Dr Eva M. Eicher and Sallie Reynolds for discussions and for haematological analyses, and Don Varnum and Sandra Murphy for technical assistance. This research is supported by grant CA 02662, US NIH. The Jackson Laboratory is fully accredited by the American Association for Accreditation of Laboratory Animal Care.

Note added in proof: Illmensee[12] transplanted single ovarian teratocarcinoma cells into genetically different blastocysts and obtained chimaeric mice with internal organ mosaicism; in one case the tumour cells populated the germ line and developed into functional eggs, giving rise to healthy offspring.

Genetic regulation of glucose phosphate isomerase in mouse oocytes

THE enzyme glucose phosphate isomerase (GPI; D-glucose-6-phosphate-ketol isomerase EC 5.3.1.9.) catalyses the interconversion of fructose-6-phosphate and glucose-6-phosphate. In mice, the product of the GPI structural gene is a monomer and the enzymatically active dimer results from monomer aggregation[1,2]. In inbred strains, GPI is found in either of two electrophoretically distinct forms: GPI-1AA or GPI-1BB (ref. 2). Theoretically, the random association of equal numbers of A and B monomers will result in dimers in the proportion of 25%AA:50%AB:25%BB, and indeed an activity distribution of these proportions is observed when samples of purified AA and BB forms, equal in enzymatic activity are dissociated and reassociated *in vitro*[3]. It follows, then, that (1) monomer aggregation is a random process which does not distinguish the monomer types; (2) the electrophoretic forms of GPI are similar enzymatically; (3) the measured activity is linearly proportional to the amount of enzyme. Therefore, the 25%AA:50%AB:25%BB activity distribution of GPI found in the mature tissues of heterozygous mice (*Gpi-1*$^{a/b}$) (ref. 4) indicates that the *a* and *b* alleles are equally expressed. However, we show here that this is not the rule for unfertilised ova, for we have observed differences in the expression of GPI in unfertilised ova from the inbred mouse strains DBA/2J, LP/J and C57BL/6J. Mature somatic tissues do not reveal these interstrain differences. We postulate that the amount of GPI in ova is controlled by a *cis*-active regulator gene linked to the GPI structural locus. This is apparently the first characterisation of a genetic variation affecting the amount of an enzyme in the

Table 1 GPI activity in unfertilised ova

Female type from which ova obtained	GPI genotype	GPI activity (nmol per h per ovum ± s.d.)
DBA/2J	*Gpi-1*$^{a/a}$	0.36 ± 0.11
C57BL/6J	*Gpi-1*$^{b/b}$	1.59 ± 0.20
LP/J	*Gpi-1*$^{a/a}$	2.08 ± 0.22
B6D2F$_1$*	*Gpi-1*$^{a/b}$	1.07 ± 0.08
D2B6F$_1$†	*Gpi-1*$^{a/b}$	0.76 ± 0.08

Ova were obtained from mature females in which ovulation had either occurred spontaneously or had been primed (3 IU pregnant mare's serum followed 45 h later with 3 IU human chorionic gonadotropin). 8–12 h post-ovulation, the females were killed and their ova were released into Brinsters medium (Gibco) by flushing the fallopian tubes. Adhering cumulus cells were removed by incubating the ova in hyaluronidase (Sigma type IV, 75 units ml^{-1}). The ova with intact zona pellucidae were washed three times in Brinsters medium. For spectrophotometry, the zona pellucidae were removed by incubation in Pronase (0.5%) followed by three washes in Brinsters medium. The ova were recovered either singly or in groups in approximately 1 µl of medium in glass pipettes. Before analysis, these samples were stored at −80 °C for up to 4 weeks. The activity of GPI was determined spectrophotometrically[13] using pooled samples of up to eight ova. The assay mixture consisted of: 0.3 ml Tris HCl buffer, *p*H 8.0 (0.1 M Tris); glucose-6-phosphate dehydrogenase, type XII, from Torula yeast, 1 unit ml^{-1}; D-fructose-6-phosphate (Sigma, grade I) 4.65 mM; NADP, sodium salt, 2.25×10^{-1} mM. Three replicate assays per vum type were carried out at room temperature in a Guilford, model 250, spectrophotometer. The rate of the reaction was constant and linear during the assay period (25 min). All values, as assessed by the *t* test, are significantly different (<0.05) from their nearest neighbour. B6D2F$_1$ and D2B6F$_1$ ova were expected to have intermediate and similar activities. Ova from these reciprocal F$_1$ hybrids had GPI-1 activities between the two parental classes but they were not identical. The relatively small difference in GPI-1 activity between the two types of F$_1$ hybrids may result from a maternal effect, but this requires further investigation.

* B6D2F$_1$ female; progeny of C57BL/6J female and DBA/2J male.
†D2B6F$_1$ female; progeny of DBA/2J female and C57BL/6J male.

Fig. 1 GPI phenotype in red blood cells (RBC) and ova. Starch gel electrophoretogram[4] demonstrating GPI expression within a heterozygous (*Gpi-1*$^{a/b}$) B6D2F$_1$ mouse. GPI in RBC demonstrates the expected proportions (25%AA:50%AB:25%BB) whereas ova demonstrate a pattern skewed in favour of GPI-1BB (3.4%AA:29.9%AB:66.8%BB). To assist in photography of the AA band, two identical ova were combined for this sample.

Fig. 2 Gene mapping study. The optimal circumstance for comparing the relative expression of the two *Gpi-1* alleles is to investigate their products in the same ova. The electrophoretic system used here permits that analysis (see Table 2). Therefore, ova from only *Gpi-1*$^{a/b}$ backcross progeny were examined. The electrophoretograms (of the BC_1 ova) were scored visually. A recombinant would demonstrate the typical RBC pattern whereas a nonrecombinant would demonstrate the ova pattern presented in Fig. 1. *Org* represents the putative site responsible for the genetic variation of GPI activity in ova. From Table 1, we can designate *Org* as high for C57BL/6J and as low for DBA/2J

mouse ovum and it provides a unique opportunity for further exploration of gene regulation during mammalian development.

Ova were obtained from the mouse strains DBA/2J, C57BL/6J and LP/J, and their GPI activities were determined spectrophotometrically. Table 1 shows that these ova express significantly different GPI activities, which do not seem to be correlated with the electrophoretic phenotype of GPI, as both LP/J and DBA/2J are homozygous for the same electrophoretic allele (*Gpi-1*^{a}). Nevertheless, relevant differences in the structural gene cannot be excluded on this basis alone, because the GPI structural genes in these strains could differ in ways which do not affect the electrophoretic mobility of the protein product.

As a first step in uncovering the mechanism responsible for these differences in GPI activity, ova from reciprocal F_1 hybrids between C57BL/6J (*Gpi-1*$^{b/b}$) and DBA/2J (*Gpi*-1$^{a/a}$) were examined. Although significantly different, their enzyme activities were found to be intermediate between those of ova from the parental strains (Table 1). In these F_1 ova, the expression of the two alleles may be under coordinate or individual control (see ref. 5). Coordinate control would lead to the equal expression of *a* and *b* alleles; if the two alleles were controlled individually, however, we would predict from the spectrophotometric data of the parental strains that the activity distribution would be skewed in favour of GPI-1B (Table 2). Figure 1 shows that the activity distribution is skewed. The ratio of A to B monomers is not unity but matches the ratio of the oocyte activity of the respective parental strains, indicating that in the maturing oocyte the *a* and *b* alleles are under individual control.

The electrophoretic distribution of GPI activity in all of 44 individual F_1 ova (16 ova from six B6D2F_1 females and 28 ova from seven D2B6F_1 females) was identical, indicating that the GPI phenotype of an unfertilised ovum is independent of both its prospective haploid genotype[6] and its maternal origin. Therefore, our results are consistent with a *cis*-regulation model which predicts that the major genetic variation, responsible for strain differences of ova GPI activity, lies within either the GPI structural gene or a closely linked controlling gene. We propose that this genetic variation defines a new regulator gene which we name *Org* for oocyte regulation of GPI.

To determine more precisely the site of the proposed *Org* locus, a gene-mapping experiment was carried out (Fig. 2); no recombination event between *Org* and *Gpi-1* was observed in 65 backcross progeny. Therefore, if we assume that recombination between *Org* and *Gpi-1* is possible, the upper limit (with 95% confidence) for the map distance separating the two is 4.5 map units[7].

Of the many possible mechanisms for the action of *Org*, differential degradation of dimers seems unlikely for two reasons. First, we would predict that the relative activities of GPI-1AA and GPI-1BB in hybrid ova would be similar to those observed between the ova of the parental strains (that is, 19:81) if a difference in the stability of the dimers, in the ova cytoplasm, were involved. However, the electrophoretic activity distribution of GPI closely approximates that expected if the monomers were being produced in the ratio predicted from parental activities, and not that expected from degradation of dimers. The second reason is provided by the *Gpi-1*^{c} allele. Mice homozygous for this allele produce a GPI-1CC dimer which is electrophoretically distinct from GPI-1AA and GPI-1BB forms, and the GPI-1CC homodimer is unstable. The mouse red blood cell is expected to show little or no protein synthesis and therefore is a useful preparation for examining relative protein stability[8]. In the red blood cells of mice heterozygous for the *Gpi*-1^{c} allele, although the three expected bands are present, there is relatively little activity in the GPI-1CC band[8]. However, red blood cells from reciprocal hybrids between C57BL/6J and DBA/2J strains do demonstrate the typical 25%AA;50%AB:25%BB pattern (Fig. 1) which suggests that the dimers in these mice have equal stability.

Our findings describe a genetic variation affecting the expression of an enzyme during oogenesis in the mouse. Although the enzyme profile of unfertilised ova and preimplantation embryos from 'random bred Swiss' mice has been intensively studied[9,10], ova from inbred strains have not been similarly examined. In the only other study similarly comparing ova from different inbred

Table 2 Expression of *Gpi-1* alleles in F_1 ova

Ova obtained from female of genotype	Predicted ratio of A to B monomers, if *Gpi-1*^{a} and *Gpi-1*^{b} are Coordinately* controlled	Individually† controlled	The ratio of A to B monomers determined by electrophoresis‡
B6D2F_1	50:50	19:81	21:79
D2B6F_1	50:50	19:81	18:82

* If coordinately controlled, both *Gpi-1* alleles would be equally expressed and therefore both A and B monomers will be present in equal amounts.

† From Table 1 the ratio of GPI activities of DBA/2J:C57BL/6J is 19:81. If individually controlled, the *Gpi-1* alleles would be unequally expressed and therefore A and B monomers will be present in unequal amounts, in the ratio of 19:81.

‡ Using a sensitive filter overlay technique for recovering an indirect reaction product of the GPI enzyme, it is possible to quantitate patterns on starch gel electrophoretograms[4]. The observed proportions (±s.d.) were, for B6D2F_1 ova: 5.3 ± 1.5 AA; 31.8 ± 3.0 AB; 62.9 ± 3.4 BB and for D2B6F_1 ova· 3.4 ± 1.7 AA; 29.8 ± 3.0 AB; 66.8 ± 4 5 BB. As the monomer compositions of the three GPI electrophoretic forms are known, it is possible to calculate the ratio of A monomers to B monomers for any given electrophoretogram. Let [A] and [B] represent the quantity of the respective GPI monomer types and [AA], [AB] and [BB] represent the amount of the dimer types, then the ratio of A:B monomers is ([AB] + 2[AA]):([AB] + 2[BB]).

strains, small but significant interstrain differences in lactate dehydrogenase activity were observed[11]. Therefore, it seems that biochemical data on the ova of random bred Swiss mice may not be generally representative.

We conclude that the absolute level of ova GPI activity, although strictly regulated within each strain, can vary over a considerable range and yet permit successful reproduction. This situation now provides a unique opportunity for further exploration into developmental gene regulation during oögenesis and also during preimplantation development[12,13].

A better cell line for making hybridomas secreting specific antibodies

FUSION of myeloma cells which grow in tissue culture with spleen cells from an immunised mouse provides a general method for obtaining cell lines (hybridomas) which make antibody of the desired specificity[1–3]. Hybrids derived from these myelomas make the immunoglobulin (Ig) heavy and light chains of the myeloma parent as well as the antigen-specific heavy and light chains of the spleen cell parent. In conditions in which the two heavy and two light chains associate randomly, a hybridoma would make 10 distinct Ig molecules, and the specific antibody would comprise only 1/16 of the total Ig[4,5]. To obtain hybridomas making only the specific antibodies requires a tumour cell fusion partner that itself makes no Ig but which can nevertheless be fused with spleen cells to obtain hybrids secreting only the specific antibody. We report here the identification of such a cell line, Sp2/0-Ag14.

Sp2/0-Ag14 was isolated as a re-clone of Sp2/HL-Ag, itself derived in several steps from Sp2/HLGK, a hybrid between a BALB/c spleen cell contributing a $\gamma 2b$ (H) and κ (L) chain with anti-sheep red blood cell activity and the myeloma cell line X63-Ag8 (γ (G) and κ (K))[2]. Sp2/0-Ag14 is resistant to 20 μg ml^{-1} 8-azaguanine, dies in HAT supplemented medium and synthesises no Ig chains. It has about 73 chromosomes which is only eight more than the chromosome number of X63-Ag8, a cell line commonly used to generate hybridomas.

Sp2/0-Ag14 was fused with spleen cells of mice immunised with trinitrophenyl derivatised keyhole limpet haemocyanin (TNP-KLH) to generate hybridomas making TNP-specific immunoglobulin (Fig. 1). Fusions were done with either polyethylene glycol (PEG) 1500 or Sendai virus, and transferred to medium either containing or lacking mouse peritoneal exudate cells. Growth was observed in only eight culture wells, all from the set that were fused with PEG and grown with peritoneal exudate cells.

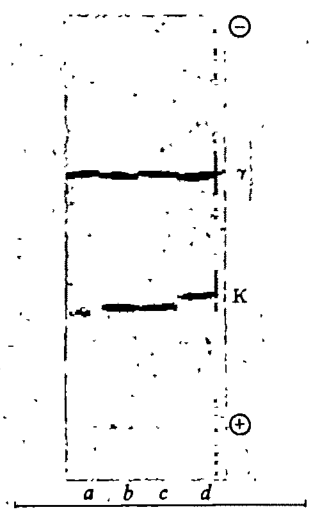

Fig. 1 Immunoglobulin from TNP-specific hybridomas analysed by SDS-polyacrylamide gel electrophoresis. To obtain hybridomas making Ig specific for the hapten trinitrophenyl, BALB/c mice were immunised i.p. with trinitrophenyl-derivitised keyhole limpet haemocyanin (TNP-KLH) (from H. Kiefer), first with 100 μg TNP-KLH contained in 0.2 ml emulsion of 50% phosphate-buffered saline (PBS), 50% complete Freund's adjuvant (Difco). 35 days later a second injection of 100 μg TNP-KLH in 0.2 ml PBS was made i.p., and 5 days later the spleens of these mice were prepared for fusion. Fusion with PEG 1500 was as described by Galfre *et al.*[9], except that the medium used was R medium, RPMI 1640 medium (Gibco) supplemented with 30mM HEPES (Flow). Here 3×10^7 Sp2/0-Ag14 and 5×10^7 spleen cells were centrifuged together at 200 g for 5 min and resuspended slowly in 0.6 ml 50% PEG in Dulbecco's modified Eagle's medium (Flow). After 1 min at 37 °C, 20 ml of R medium was added slowly. The cells were then centrifuged and resuspended in 20 ml of R medium supplemented with 10% fetal calf serum (Gibco) (RF medium) and 0.2 ml of this suspension was then distributed to each of 200 wells containing 0.8 ml RF medium. One hundred of these wells also contained 2×10^5 mouse peritoneal exudate cells. After 24 h incubation, 1 ml RF supplemented with hypoxanthine, aminopterin and thymidine (HAT) was added to each well. Every 2–3 days, 1 ml of the medium was replaced with fresh RF+HAT. After 2 weeks, growth was observed in eight wells of the peritoneal exudate supplemented wells and the cultures were tested for immunoglobulin production by testing the culture medium for lysis of protein A coated sheep red blood cells (SRC) for nonspecific Ig[10] and of TNP coated SRC[2] (for TNP specific activity). After 1–2 months the cells from TNP-specific wells were cloned by plating in soft agar[11] or in methyl cellulose[12]. The soft agar clones were overlaid with TNP coated SRC, and clones lysing the TNP coated SRC were transferred to liquid medium. The cells were grown in the presence of ^{14}C leucine to label secreted Ig which was analysed by SDS polyacrylamide gel electrophoresis as described[11]. The hybridoma cell lines analysed were hy5.19 (*a*), hy2.15 (*b*), hy1.2 (*c*) and hy3.3 (*d*).

Supernatant of four of the eight growth-positive wells lysed protein A but not TNP-coated sheep red blood cells (SRC) suggesting that the Ig made by these cells did not have TNP specificity. The Ig secreted by these cells was analysed by SDS-polyacrylamide gel electrophoresis (SDS-PAGE) and found to be IgM (data not shown). The remaining four growth positive wells lysed both TNP and protein A SRC and cells from these wells were cloned and analysed further, as described below. SDS-PAGE analysis suggested that these cell lines secreted IgG (Fig. 1). Ouchterlony analysis of culture supernatants using class-specific antisera (Litton Bionetics) indicated that hy1.2 makes an IgG2a, and that hy2.15, hy3.3 and hy5.19 make IgG1 and that all four TNP-specific hybridomas make a κ light chain. The SDS-PAGE analysis shown in Fig. 1 indicates that the clones can be distinguished by the mobility of the light or heavy chain, implying that these cell lines are making different antibodies.

We have examined the TNP-specific hybridomas for re-expression of the SRC-specific IgG2b of the progenitor cell line Sp2/HL-Ag14 by testing for SRC-specific plaques. No plaques

0028-0836/78/0276—0269$01 00

were found and we conclude that revertants constitute fewer than one in 5×10^4 of the TNP-specific hybridoma cells.

The karyotypes of the TNP-specific cell lines provide evidence that these cells are hybrids of Sp2/0-Ag14 and mouse cells. Normal mouse cells and Sp2/0-Ag14 contain 40 and 73 chromosomes, respectively. The TNP-specific cell lines hy1.2, hy2.15, hy3.3 and hy5.19 contain approximately 100, 105, 106 and 99 chromosomes, respectively, and we suppose that fusion yielded hybrids that segregated better growing cells that had lost 7–14 chromosomes.

Evidence has been presented that X63-Ag8 cells preferentially fuse with the dividing cells of the spleen[2,6,7], which for the B-cell compartment consist mainly of Ig-secreting, plaque-forming cells. Sp2/0-Ag14 seems to display the same preference. In the population of spleen cells used for this fusion, approximately 0.4% of the cells made indirect (IgG) TNP-specific plaques and 0.004% made direct (IgM) TNP plaques. Assuming that 1% of the spleen cells are plaque forming cells[8] one would anticipate that about 40% of the hybridomas would make IgG with TNP specificity, as was observed. On the other hand, about 90% of the nonspecific plaque-forming cells of the spleen make IgM rather than IgG[8], so that one would anticipate that among the nonspecific hybridomas, 90% would also make IgM, a figure that is consistent with our observation that all four nonspecific hybridomas examined made IgM.

To obtain high-titre preparations of the TNP-specific Ig, 10^6 TNP-specific hybridoma cells were injected intraperitoneally into BALB/c mice. All caused tumours and yielded ascites fluid with titres generally about 100 times higher than for the culture supernatants.

The efficiency of fusion with Sp2/0-Ag14 has been variable. In our early experiments, such as the fusion described above, we obtained fewer hybrids than we ordinarily obtain with X63-Ag8. However, in more recent experiments, fusions with Sp2/0-Ag14 have often been more efficient, in particular in fusions with lipopolysaccharide stimulated spleen cells or with large spleen cells (F. Melchers, Clark and G.K., unpublished observations). We consider that Sp2/0-Ag14 can yield as many hybrids as X63-Ag8.

Alternative methods exist for obtaining hybridomas that do not express the myeloma Ig. It has been possible to isolate re-clones that have lost the expression of the nonspecific heavy or light chains[2]. This problem has been reduced by fusing with NSI-Ag 4/1, a derivative of X63 that makes the κ but not the $\gamma 1$ chain of the myeloma[2]. We anticipate that Sp2/0-Ag14 will prove yet a better cell line for generating hybridomas making truly monoclonal antibodies.

Activation of latent Epstein–Barr virus by antibody to human IgM

EPSTEIN–BARR VIRUS (EBV) is the causative agent of most infectious mononucleosis[1] and is also associated with two human tumours, Burkitt's lymphoma (BL)[2] and nasopharyngeal carcinoma[2]. Lymphoid cell lines of B-cell origin have been established from patients with these diseases, and from lymphocytes transformed *in vitro* by EBV[3]. In lymphoid cell lines the lytic viral cycle is usually repressed even though the cells carry multiple copies of the EBV genome. These cells therefore provide a valuable model for the study of latent EBV infection. Although EBV is ubiquitous, its association with human malignant disease is to a large extent both ethnically and geographically restricted[2] and it is therefore of interest to understand the host factors involved in the regulation of the expression of the latent EBV genome. In infectious mononucleosis, EBV infection is associated not only with a specific anti-EBV antibody[2] and T-lymphocyte response[4] but also with an increase in nonspecific IgM production[5]. EBV-infected B lymphocytes produce polyclonal Ig (ref. 6) and the majority of established EBV genome-positive lymphoid cell lines possess surface IgM (ref. 7). We report here that treatment of several human lymphoid cell lines with antisera to human IgM activates the latent EBV genome to give a marked increase in EBV-specific early antigen (EA). Also, in some cell lines this treatment induces an increase in virus capsid antigen (VCA).

Treatment of BL-derived Raji cells with antiserum directed against human immunoglobulins increased the number of cells expressing EBV EA by up to 5,000-fold, to give 11% EA-positive cells determined by either direct or indirect immunofluorescence (Table 1), and confirmed by EA-specific complement fixation[8]. The fluorescence was specific for EA, as no positive cells were observed after staining with either control EBV-negative human serum, or with anti-VCA-positive EA-negative antiserum. EBV-specified antigens can be induced in lymphoid cell lines by halogenated pyrimidines[9,10], inhibitors of protein synthesis[11] or the tumour promotor 12-*O*-tetradecanoyl

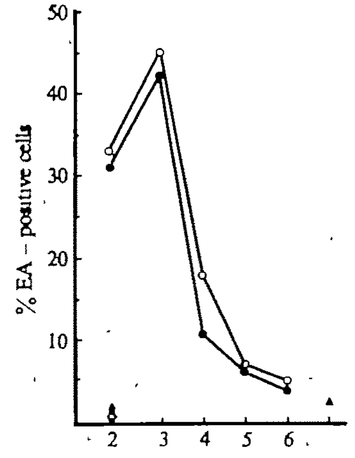

Fig. 1 Induction of EA in cultures of Raji cells treated with various dilutions of antiserum. Cells were cultivated for 72 h with a particular dilution of antiserum in the presence of IUdR ($25 \mu g\ ml^{-1}$). The number of EA-positive cells was then determined on acetone-fixed smears by indirect immunofluorescence. None of the antisera had any effect on cell viability at the dilutions shown in the figure. ○, Sheep anti-total human immunoglobulins; ●, goat anti-human IgM; □, goat anti-human IgA; ■, goat anti-human IgG; △, goat anti-human IgD; ◇, goat anti-human IgE; ▲, IUdR alone ($25 \mu g\ ml^{-1}$)

				(5.5)	(7.0)	(14.0)	(17.0)
M61	1	44	10^{-2} Anti-IgM	3.0	2.6	3 5	3.0

Lymphoid cells were cultivated in RPMI 1640 medium with 20% fetal calf serum (Gibco) in static suspension culture for the times indicated with medium alone; medium + IUdR (25 μg ml^{-1}); the dilution of antiserum indicated; or IUdR + antiserum EA or VCA was determined at this time in duplicate on 50,000 cells (fixed with acetone) either by direct immunofluorescence using FITC-conjugated EA(+) VCA(+), or EA(−) VCA(+) human sera, or by indirect immunofluorescence using EBV-specific human antisera and FITC-conjugated goat anti-human IgG globulin (Huntingdon).

* Anti-IgM antiserum was adsorbed on a column of immobilised human IgM as previously described[30]. The serum and eluate contained an equivalent concentration of anti-IgM antibody determined by quantitative immunodiffusion[31].

† In this experiment treatment of Raji cells with TPA (20 ng ml^{-1}, Sigma) gave 0.6% EA(+) cells and TPA with IUdR (25 μg ml^{-1}) gave 5.5% EA(+) cells.

‡ IUdR was removed by washing after 24 h treatment and the cells were then resuspended in either medium alone, or medium containing antiserum.

phorbol-13-acetate (TPA)[12]. In optimal conditions treatment of Raji cells with antiserum consistently gave a greater degree of induction of EBV EA than treatment of these cells with either 5-iodo-2-deoxyuridine (IUdR) or TPA (Table 1). Treatment of Raji cells with antiserum in the presence of IUdR gave a synergistic effect resulting in up to 50% EA-positive cells (Table 1).

The active component of the antiserum to total immunoglobulins was found to be anti-human IgM immunoglobulin. Thus, the EA-inducing activity of antiserum to human IgM paralleled that of antiserum to total human immunoglobulin, whereas purified antisera to human IgG, IgA, IgE and IgD were all inactive (Fig. 1).

The activity of the anti-human IgM antiserum was specific for human IgM, as the EA-inducing activity of the antiserum was removed after passage through a column of immobilised IgM and could be recovered after elution of the column (Table 1). The effect of the anti-IgM antiserum was due to its anti-μ-chain activity, as antisera against the light chains λ or κ were inactive. Normal human, sheep, goat and rabbit sera were all inactive as were antisera against human lipoprotein, β_2 macroglobulin and albumin. Raji cells have been reported to exhibit on their surface, in addition to IgM (ref. 13), a receptor for the Fc fragment of immunoglobulin[14], a receptor for the C3 component of complement[15], HLA histocompatibility antigens[16], β_2 microglobulin[16] and 'Ia'-like antigens[17]. However, no increase in EA-positive cells was observed when Raji cells were treated with complement (either alone or in the presence of anti-C3), anti-β_2 microglobulin antisera, specific anti-HLA antisera or specific anti-Ia antisera. Similarly, treatment of Raji cells with anti-human immunoglobulins in conditions which gave good induction of EA had no effect on the subsequent binding of IgG to the Fc receptor, or aggregated IgG in the presence of complement to the C3 receptor of Raji cells, as determined by the use of anti-human IgG labelled with ^{125}I-*Staphylococcus* protein A (ref. 18) (data not shown).

An EBV-specified DNA polymerase is thought to be one of the virus-coded proteins which constitute EA antigen[19].

Table 2 Incorporation of ^{3}H-thymidine and ^{3}H-IUdR in Raji cells treated with anti-IgM antiserum

Labelled precursor	Sample	c.p.m. per 10^6 cells		Specific activity (c.p.m. per μg DNA)	
^{3}H-thymidine	Control	227,811 ± 17,307	NS	21,048 ± 1,869	NS
	10^{-2} anti-IgM	208,288 ± 58,611		21,212 ± 955	
^{3}H-IUdR	IUdR	27,511 ± 2,515	NS	12,798 ± 1,290	NS
	IUdR + 10^{-2} anti-IgM	25,475 ± 3,310		12,319 ± 1,911	

Raji cells were cultivated in stirred suspension culture for 24 h with either 0.5 μCi ml^{-1} ^{3}H-thymidine (25 Ci mmol^{-1}, CEA) or 0.5 μCi ml^{-1} ^{3}H-thymidine + 10^{-2} dilution of anti-IgM antiserum (Merieux), or 2 μCi ml^{-1} ^{3}H-IUdR (2.7 Ci mmol^{-1}, Amersham) + 25 μg ml^{-1} cold IUdR, or 2 μCi ml^{-1} ^{3}H-IUdR + 25 μg ml^{-1} cold IUdR + 10^{-2} dilution of anti-IgM antiserum. Incorporation of labelled precursors into cellular material was determined by measuring the radioactivity in the trichloroacetic acid-insoluble material retained on a Millipore filter as previously described[32]. The specific radioactivity of purified DNA was determined after extraction of the DNA as previously described[33]. NS, Not significant.

Treatment of Raji cells with anti-IgM antiserum, in conditions which gave a good induction of EA, also caused a marked increase in the activity of the virus-specified DNA polymerase (T. Ooka, G. L., M. G. T., unpublished results). Anti-μ antibody can activate B lympocytes *in vitro*[20,21], leading to antibody production and the stimulation of ^{3}H-thymidine incorporation. However, treatment of Raji cells with anti-μ antibody had no significant effect on either the incorporation of ^{3}H-thymidine or ^{3}H-IUdR into cellular acid-precipitable material or on the specific radioactivity of the purified DNA (Table 2), suggesting that EA induction by anti-μ antibody cannot be explained simply as a nonspecific mitogenic effect.

In agreement with previous reports[22–25], no VCA-positive Raji cells were observed after short-term induction with IUdR or even in cultures treated with anti-IgM antiserum and IUdR, where 50% of the cells were EA positive. Our results suggest that the block in the abortive cycle of Raji cells is after EA and DNA polymerase synthesis and is independent of the level of induction. BL-derived Daudi cells, however, contain surface IgM and are capable of entering a lytic cycle. Treatment of Daudi cells with anti-IgM antibody markedly increased the number of both EA- and VCA-positive cells (Table 1). Treatment of the BL-derived BJAB-B95-8 cell line with anti-IgM antiserum gave up to a 2,000-fold increase in EA-positive cells, although no VCA-positive cells were observed either before or after treatment with antiserum. Some increase in EA (but not VCA) positive cells was obtained in anti-IgM-treated cultures of P3HR-1 cells (Table 1). Anti-IgM antiserum had no effect on the expression of EBV-specified antigens in the lymphoma-derived M61 cell line[25], one of the rare lymphoid cell lines which have surface immunoglobulin predominantly of the IgG class (Table 1). Thus, differences in the amount and/or expression of surface-bound IgM may partly explain variations in the response of different cell lines to the anti-IgM antibody, although the nature of the interaction between viral and cellular genomes is also probably important.

We have shown that anti-IgM antiserum is a more efficient inducer of EBV EA in Raji cells than either of the two most potent chemical inducers, IUdR or TPA, and the use of anti-IgM serum together with IUdR should facilitate the large-scale production of virus-specified antigens and DNA polymerase. However, the main interest of our results is that treatment of lymphoid cells with specific antisera against human IgM leads to activation of the latent EBV genome. The specificity of this interaction (that only anti-IgM antibody activates the EBV genome) suggests that this effect is probably mediated through an interaction of the antiserum with IgM on the cell surface. Activation may result either from a direct stimulation of virus replication by the antiserum, or from combination of the antiserum with surface-bound immunoglobulin which may play a part in the maintenance and perhaps even in the establishment of the latency of EBV infection in human lymphoid cells. It is perhaps relevant that the majority of these cells possess surface immunoglobulin of the IgM class[7]. EBV has been shown to infect B lymphocytes selectively[27] and to stimulate immunoglobulin production in these cells[6]. There is also evidence to suggest that EBV may preferentially transform IgM-carrying lymphocytes[28,29]. It may well be that immunoglobulin production may in turn be related to the regulation of latent EBV infection in these cells. Our results, in addition to demonstrating a very efficient means of inducing EBV-specific antigens, may therefore have some bearing on the mechanism of the latency of EBV infection and its association with human disease.

We thank Dr I. Gresser for his advice, Drs P. Burtin, E. Mogensen and P. Sheldrick for discussions, Dr T. Ooka for the assay of the DNA polymerase, Dr H. Tapiero for help with DNA extraction, Dr P. Verroust for help with the radioimmune assay and the purification of antihuman IgA, IgG and IgM, Mrs M. Berthelon and Mrs M. Lavoue for help with the serology, and Drs H. Betuel, M. Fellous, H. Fridman, J. -P. Revillard and C. Vincent for the antisera. Other antisera were prepared in our laboratories or purchased from Bionetics, Cappel or Nordic. This work was supported in part by grants from DRET (77-203), INSERM (CRL 77-4-072-1) ATP (47-77-79) and NCI (contract no. ICP 43296).

Retinoids block phenotypic cell transformation produced by sarcoma growth factor

MURINE SARCOMA VIRUS (MSV)-transformed cells lack available receptors for epidermal growth factor (EGF)[1,2]. We have shown that this altered phenotype is the result of the endogenous production of growth factors by the MSV-transformed cells themselves. The major activity, isolated and purified from transformed cells, has been found in a 12,000-molecular weight peak and competed with EGF in an EGF-receptor-binding assay[3]. This growth factor, called sarcoma growth factor (SGF), stimulates cell division, causes normal cells to grow in soft agar and produces rapid, reversible morphological transformation of cells in monolayer culture[3]. There is no evidence that SGF acts as a complete carcinogen, producing permanent cell transformation; its properties resemble classical chemical promoters of carcinogenesis, like 12-*O*-tetradecanoylphorbol-13-acetate (TPA)[4–6], the highly active component of croton oil. Whereas TPA is an exogenous plant derivative acting on an animal or a cell, SGF is an endogenous,

Table 1 Effect of SGF and retinyl acetate on the final cell density of rat fibroblast cell cultures

Treatment	Cells per plate ($\times 10^{-6}$) Expt 1	Expt 2
Untreated control	1.2	1.0
+Retinyl acetate (1.9×10^{-8} M)	1.3	1.1
SGF-treated (10 μg ml^{-1})	3.6	2.6
+Retinyl acetate (1.9×10^{-8} M)	1.4	0.9
+DMSO (1:1,000)	3.3	2.5

A subclone (536–7) of a normal rat fibroblast cell clone, NRK 49F (ref. 17), susceptible to the growth-stimulating effect of SGF (ref. 3), was seeded at 2×10^5 cells per plate in 60-mm plastic Petri dishes. The cells were treated at the time of inoculation and refed with medium (Dulbecco's modified medium with 1% fetal calf serum) containing the additions shown every third day. Cell counts were made 10 d after seeding. The SGF came from supernatants of MSV-transformed mouse NIH/3T3 cells as described previously[3]. Retinyl acetate was dissolved in dimethyl sulphoxide (DMSO). The final concentration of DMSO in all experiments was 0.1%. Neither retinyl acetate nor DMSO alone showed any effect on the growth, final cell density or cloning efficiency of the normal rat fibroblasts at the concentrations used.

virally induced growth promoter. In this respect it is interesting that retinoids (vitamin A and synthetic analogues)[7] block the action *in vivo* of exogenous and endogenous promoters, preventing carcinogens from producing new tumours, but do not reverse the growth of many established tumours[7–10]. Retinoids prevent cancer of the lung[7,11], skin[9], bladder[12] and mammary gland[13] in experimental animals, block cell transformation induced by chemicals[14] and radiation[14,15] in culture, and reverse the anchorage-independent growth of transformed mouse fibroblasts[16]. If SGF is part of the natural tumour-promoting system and retinoids are part of the natural defence against that system, then one should be able to demonstrate a direct antagonism in cell culture. This report establishes that this happens.

We have used a subclone (536–7) of a rat fibroblast cell clone (NRK 49F)[17] that showed pronounced morphological transformation and anchorage-independent growth when treated with SGF, forming multiple cell layers and criss-crossing each other in an apparently random fashion. Although the effects are all reversible, these treated cells resemble MSV-transformed cells in their phenotype[3]. The cells which were treated with both SGF and retinoids did not have a disordered growth pattern. Table 1 shows that retinyl acetate, at 6 ng ml^{-1}, almost abolished the growth-stimulatory effect of SGF, as determined by the final cell density reached by the monolayer cultures 10 d after the experiment began. The effect of retinoids on SGF-induced morphological alterations was evident within a few days of treatment.

The retinoid concentrations ($1-2\times10^{-8}$ M) neither reversed the phenotype of virally transformed cells, nor blocked cell transformation produced by transforming viruses, such as the Moloney strain of mouse sarcoma virus (MSV) or simian virus 40 (SV40). Mouse 3T3 cells and rat fibroblasts were tested for susceptibility to transformation by MSV and by SV40. Neither retinyl acetate nor retinoic acid, up to 2×10^{-6} M, could be demonstrated to block either the initiation or the maintenance of virally induced transformation when efficient transforming viruses like MSV or SV40 were used (data not shown). In the same experiment, however, the SGF-induced morphological transformation was inhibited. Retinyl acetate did not inhibit normal cell growth or the cloning efficiency of the rat fibroblast cell clones in Petri dishes (data not shown), but did have a pronounced effect on the final cell ('saturation') density of cells treated with SGF (Table 1). SGF-induced cell growth was blocked and normal growth properties were essentially retained.

Table 2 shows that at concentrations well below those which produce any evidence of toxicity, retinoids prevent SGF-induced colony formation in soft agar. Colonies which did form were smaller and contained fewer cells than those treated with SGF alone. Retinoic acid, retinyl acetate, retinyl methyl ether and retinylidene dimedone were all effective. Cells not treated with SGF and plated in agar remained as single cells with occasional 2–4-cell colonies. The clone used has a spontaneous transformation rate, as determined by agar colony growth, of less than one in 10^6 cells plated. The preparation of SGF used, at 10 μg ml^{-1}, produced 40–50 large colonies per 10^4 treated cells and also many smaller colonies of 4–20 cells. The inhibitory effect of the retinoids was less evident or absent when more active SGF preparations or higher concentrations of SGF were used. Of the compounds tested, retinylidene dimedone was the most efficient inhibitor of SGF-induced phenotypic transformation (Table 2, expt 3). As a control against selective toxicity of retinoids to transformed cells as compared to normal cells, MSV-transformed mouse and rat cells which grow well in agar without SGF were plated in soft agar in the presence of retinyl acetate at 2×10^{-6} M. No reduction in colony-forming ability was seen.

These preliminary experiments establish that, in the system used here, retinoids block the transforming effect of the polypeptide hormone, SGF. Only one concentration of each retinoid, well below the level that produces any cell toxicity, was used, and both the growth promoter and the antagonists were added to the cells at the same time. This system is now available for further studies where the concentrations, duration of treatment and the nature of the interaction between each of the three components (promoter, antagonist and responding cell clone) can be varied in a systematic manner.

The general transformation model we propose has the following features. Viruses and chemical carcinogens act by inducing cells to produce normally repressed or inactive growth-promoting factors. These factors, which may be endogenous or exogenous to given cells, could be important in embryonic development, but if inappropriately expressed later in life could lead to transformation. Tumour viruses either provide transforming genes directly or activate cellular genes; chemical carcinogens do only the latter. These growth-promoting and

transforming factors may be produced during early embryogenesis and then 'switched off'. The endogenous viruses, with their capacity to recombine with cellular genes, have the ability to transfer information between cells and presumably within a cell, like bacterial insertion sequences. They may well be vehicles which allow expression of the endogenous growth-promoter structural genes. In this model the promoters, be they endogenous (SGF) or exogenous (TPA) act as proximal effectors of transformation.

In certain interpretations of the two-step theory of carcinogenesis, initiation involves gene damage[4,18]; we suggest that this damage may facilitate the production of normally repressed growth factors and/or their cellular receptors. Exogenous promoters interact with specific membrane components and produce reversible phenotypic effects[6,19,20]. Treatment of cells with either SGF or TPA causes a reduction in the number of available EGF – receptor sites on cells[1,21]. SGF is a peptide hormone structurally similar to EGF; it is an acid- and heat-stable polypeptide with disulphide bonds and with an active component of a molecular weight 12,000 (ref. 3). The diterpenoid TPA (molecular weight 616), on the other hand, is structurally very different[5,22,23], and its effect on promoter-induced phenotypic change and/or competition for available EGF membrane-binding sites is not clear. Initiated cells may already be producing some of their own growth factors but not in sufficient quantity to cause phenotypic transformation. However, additional exogenous promoter would allow a critical concentration for transformation to be reached. A defined system, using cloned cells in culture to study natural tumour promoters and their antagonists, as described here, should permit a more precise analysis of the mechanisms of carcinogenesis.

The virogene–oncogene hypothesis[24] points out the possibly erroneous assumption that virally induced tumours would have to arise through external infection by emphasising that virus-coded or virus-associated genes are already present in several animal species. These genes, rather than the environmentally transmissible agents, are more likely to be involved in the origin of natural cancers. The tumour viruses, although unnatural, in that they have often been selected for producing rapid disease, have provided extremely powerful tools to dissect out and understand the molecular mechanisms involved. Genetically transmitted viral genes and transforming genes are now accepted as part of the normal genetic make-up of many organisms and as being activated by agents such as chemical carcinogens, hormones and radiation[25,26]. In parallel with this is the frequently made assertion that chemical, environmental or even industrial carcinogenesis, are almost interchangeable with one another. The finding that SGF, produced by animal cells themselves, is an extremely potent promoter in cell culture systems suggests that endogenous growth promoters may be significant factors in naturally occurring cancers.

In view of the efficacy with which an endogenous factor such as SGF promotes transformation, natural mechanisms for suppression of transformation must exist. The data presented here, as well as previous *in vivo* studies, indicate that suppressors of transformation, such as retinoids, offer a potential approach to prevent the expression of the transformed phenotype.

We thank BASF Aktiengesellschaft, Hoffmann-La Roche, Johnson & Johnson, Nancy Acton and Arnold Brossi for the retinoids, and Patricia Johnson, Yvette Preston, Charlotte Meyer and Dianne Newton for technical assistance. The 5,5-dimethyl-2-retinylidene-1,3-cyclohexanedione was synthesised by Drs Nancy Acton and Arnold Brossi (unpublished observations).

Retinoids as well as tumour promoters enhance deacylation of cellular lipids and prostaglandin production in MDCK cells

IN terms of a multiple-stage model of chemical carcinogenesis, tumour promoters may block differentiation of initiated (somatically mutated) cells and permit sufficient cell proliferation to overcome growth suppression[1,2]. Deacylation of cellular lipids, arachidonic acid metabolism, or both, are biochemical pathways that accompany the effects of tumour promoters and may even mediate cellular differentiation and carcinogenesis[3]. While investigating the effects of several putative anticarcinogenic compounds, we found and report here that retinoids, like the tumour-promoting phorbol diesters, stimulated deacylation of cellular lipids and prostaglandin production in dog kidney

Table 1 Effect of retinoids on PGE_2 and $PGF_{2\alpha}$ production by MDCK cells

+TPA	172.3 ± 1.4*	5 20 ± 0.58*†	12.67 ± 0.58*	22.67 ± 0.58*

MDCK cells were treated for 22 h with TPA (0.0005 μg ml^{-1}, Consolidated Midland), *cis* retinoic acid (2 μg ml^{-1}, Roche), TMMP retinoic acid (2 μg ml^{-1}, Roche) or their mixture. Prostaglandins produced were analysed by radioimmunoassay. Production of 6-keto-PGF$_{1\alpha}$ by MDCK cells was verified by high pressure liquid chromatographic analyses[21] The values are the mean ± s.d. of triplicate dishes. The differences between 'none' and *cis* retinoic acid or TMMP retinoic acid are statistically significant. The differences between 'none' and TPA; *cis* retinoic acid and *cis* retinoic acid plus TPA; and TMMP retinoic acid and TMMP retinoic acid plus TPA are statistically significant ($P<0.001$). The differences between TPA and *cis* retinoic acid plus TPA are not statistically significant. Those between TMMP retinoic acid plus TPA and TPA or *cis* retinoic acid plus TPA are statistically significant.

* $P<0.001$. † $P<0.005$.

(MDCK) cells. Treatment of the cells with a phorbol diester and a trimethylmethoxyphenyl analogue of retinoic acid led to a synergistic stimulation of lipid deacylation and prostaglandin production.

The MDCK cells were grown in Eagle's minimal essential medium containing 2 mM L-glutamate and supplemented with 10% (v/v) fetal bovine serum and penicillin–streptomycin. Cells were plated at 2×10^5 cells per dish and incubated in non-serum-supplemented medium with and without increments of retinoids and/or the phorbol diester for 22 h. Triplicate dishes were used for each reagent. Medium was assayed serologically for PGE$_2$, PGF$_{2\alpha}$, and 6-keto-PGF$_{1\alpha}$, with anti-PGE$_2$, anti-PGF$_{2\alpha}$ and anti-6-keto-PGF$_{1\alpha}$ antisera (the anti-PGE$_2$ antiserum reacts 0.01% with PGF$_{2\alpha}$ and the anti-PGF$_{2\alpha}$ antiserum reacts 0.1% with PGE$_2$, but the antisera do not identify the prostaglandins as either monoenoic or dienoic). The MDCK cells were labelled with ^{3}H-arachidonate as described previously[4]. They were extracted with 2:1 chloroform:methanol and the extract chromatographed on thin-layer silica gel G (Merck). Analysis of the radioactive materials showed that 69% of the radioactivity was associated with phospholipids, 15.0% with triglycerides, 11% with unidentified materials, 3.4% with prostaglandins and 1.4% with free arachidonic acid.

MDCK cells incubated in the presence of the trimethylmethoxyphenyl (TMMP) analogue of retinoic acid produced increased levels of PGE$_2$ and PGF$_{2\alpha}$. This stimulation was observed with as little as 0.1 μg ml^{-1} (2.7×10^{-7} M) TMMP retinoic acid (Table 1). At the concentrations of retinoids used, the number of cells adherent to the culture dish was not affected, although higher levels of some of the retinoids (~3×10^{-5} M), especially *cis* and *trans* retinoic acid and retinyl acetate, did detach cells from the dish. The stimulating activities of the different retinoids varied (Table 1). All the retinoids stimulated prostaglandin production, except retinyl palmitate, which, at levels >5.0 μg ml^{-1}, inhibited prostaglandin production. However, this inhibition could be accounted for by its content of the phenolic antioxidant, butylated hydroxyanisole, used as preservative, which inhibits prostaglandin production (K.O. and L.L., unpublished data).

The synthesis of the prostaglandins by MDCK cells is limited by the availability of the precursor polyunsaturated fatty acids[5]. Stimulation of deacylation of the cellular lipids was demonstrated by the release of radioactive materials from ^{3}H-arachidonic acid-labelled cells treated with *cis* retinoic acid or TMMP retinoic acid (2.0 μg ml^{-1}, Table 2). Levels of PGE$_2$, PGF$_{2\alpha}$ and the prostacyclin non-enzymatic product, 6-keto-PGF$_{1\alpha}$, were also increased. The tumour-promoter, 12-*O*-tetradecanoylphorbol-13-acetate (TPA), was even more effective than the retinoids at stimulating release of radioactive materials and enhancing prostaglandin and prostacyclin production. The stimulating effects of both TPA and TMMP retinoic acid were more than additive; they acted in a synergistic manner. The effects of *cis* retinoic acid and TPA were not synergistic; in fact, their combined effect was slightly less than additive.

Studies of the effects of vitamin A and its analogues on carcinogenesis have led to conflicting results. On the one hand, they modify skin tumour promotion and prevent epithelial cancers[6–10]. Topical applications of retinoids inhibit skin papilloma formation and the tumour-promoting phorbol diester induction of ornithine decarboxylase activity[11]. However, enhancement of the effects of the chemical carcinogens, similar to that of the tumour-promoting phorbol diesters, has also been described[12–15]. With respect to cultured cells, pathways leading to membrane glycosylation may involve vitamin A as a lipid intermediate[16,17] and vitamin A can alter surface membrane glycolipids and glycoproteins[18]. Retinoic acid inhibits the co-mitogenic action of TPA in bovine lymphocytes[19], and retinoic acid and retinoids, at low concentrations, stimulate plasminogen-activator synthesis in chick embryo fibroblasts; at suboptimal levels of TPA, the effects of retinoic acid and TPA are synergistic[20]. Clearly, the biological properties of the retinoids are manifold and their promoting or anticarcinogenic properties may depend on the type of membrane change induced, which probably in turn depends on the cell and the particular synthetic retinoid used. We suggest that the use of vitamin A and some of its analogues to prevent chemical carcinogenesis is premature; they may enhance, not inhibit tumour formation.

Unless indicated, the retinoids were from Sigma.

Uncoupled synthesis of histones and DNA during Friend cell differentiation

ERYTHROLEUKAEMIC mouse spleen cells (Friend cells) can undergo erythropoietic differentiation *in vitro* when cultured in the presence of a variety of different inducers[1–6]. Untreated Friend cells are arrested at a proerythroblast-like stage of development in the erythropoietic lineage[7] and contain little or no globin mRNAs and no haemoglobin. In response to an inducer the cells start transcribing the globin genes, accumulate globin mRNAs and haemoglobin in the cytoplasm[3,8] and express morphological and biochemical changes which parallel changes observed during normal *in vivo* erythropoiesis in the mouse. Dimethyl sulphoxide-induced Friend cells (strain 745 A) show a transient block in the initiation of DNA synthesis which precedes detectable expressions of the differentiated functions[9]. We report here a G1 phase prolongation in another Friend cell line using another inducer (*n*-butyrate). We have also characterised the induction process in respect of the capacity of the cells to synthesise and transport proteins to the nucleus. The rate of synthesis of total nuclear proteins decreases steadily but the histones show a reproducible pattern of an initial increase in this parameter at a time when DNA synthesis is blocked, indicating that histone synthesis becomes independent of DNA replication during Friend cell differentiation.

A series of cultures was prepared starting from a single culture of F4N cells[10] in exponential growth. *n*-Butyrate was added and at various times thereafter cells from one culture were collected for determination of cell density, incorporation by whole cells of [methyl-^{3}H]thymidine into acid-precipitable material and appearance of radioactive label in total nuclear proteins and in histones after labelling of cells with ^{3}H-lysine and ^{3}H-arginine. The results of such an experiment are shown in Fig. 1. In Fig. 1*a* cellular DNA synthesis after addition of *n*-butyrate is related to the percentage of haemoglobin-containing, benzidine-reactive (B$^+$) cells[6]. For 4 h after addition of inducer the rate of DNA synthesis was unchanged but between 4 and 8 h after addition DNA synthesis decreased to half the original rate. This low-level DNA synthesis continued until 12 h after addition of inducer, when the rate of DNA synthesis increased to levels characteristic for exponentially growing cells: this period was followed by a final cessation of DNA synthesis. A significant increase in the number of haemoglobin-producing cells was observed only at about 20 h after the onset of *n*-butyrate treatment. The DNA synthesis curve and cytofluorometric determination of the DNA content of single cells suggest that an early effect of the induction process is a transient prolongation of the G1 period of the cell cycle resulting in an extensive depletion of S-phase cells[11]. A similar prolongation has been described for dimethylsulphoxide-induced Friend 745A cells[9] although the time scale for the changes is different. *n*-Butyrate acts much more rapidly than dimethylsulphoxide in inducing the expression of the differentiated function as monitored by the appearance of B$^+$ cells. In accordance with this the prolongation of the G1 phase in our system is expressed both earlier and is of shorter duration than the prolongation observed with dimethylsulphoxide[9]. The G1 phase prolongation seems to be an inherent feature of the commitment process and might be necessary for the synthesis of specific regulatory substances required during the following S phase. This first S phase in the presence of the inducer seems to be unusual in some respects: the activity of the nuclear enzyme poly (ADP-ribose) polymerase is two- to fourfold greater, and

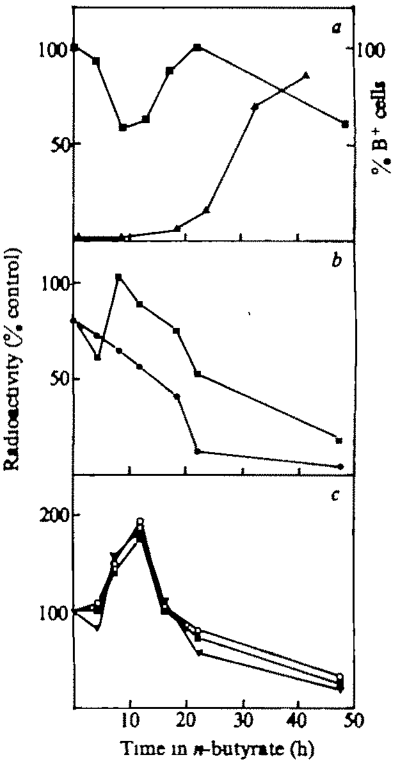

Fig. 1 Rate of DNA synthesis and appearance of newly synthesised proteins in the nuclei of *n*-butyrate-treated F4N cells. Ostertag's erythroleukaemic mouse spleen cell line F4N was used[2] and cells were kept in culture conditions described previously[10]. For induction of the erythropoietic differentiation 1 mM *n*-butyrate was added to culture medium supporting exponentially growing cells (2–3 × 10^5 cells ml^{-1}) and cells were kept for various periods in the presence of the inducer. *a*, Incorporation of ^{3}H-thymidine into DNA (c.p.m. per 10^3 cells) (■) and appearance of benzidine reactive (B$^+$) cells (▲). For the measurement of DNA synthesis 1-ml aliquots of cells that had been kept in *n*-butyrate for the time shown on the abscissa were incubated with 3 μCi [methyl-^{3}H]thymidine (50 Ci mmol^{-1}) for 20 min at 37 °C. Trichloroacetic acid (TCA) precipitable material was determined by liquid scintillation counting. The percentage of benzidine reactive cells was determined using the suspension staining technique[10]. Between 200 and 300 cells were counted for each determination *b*, The appearance of newly synthesised proteins in the nuclear fraction of *n*-butyrate-treated cells (total nuclear proteins, ●, histones, ◆) expressed as per cent of untreated, exponentially growing cells was determined as follows. In sterile conditions 3–5 × 10^7 cells were collected, washed once with 5 ml lysine- and arginine-free culture medium, resuspended in 3 ml of the same medium which was substituted with 50 μCi ^{3}H-lysine (74 Ci mmol^{-1}) and 50 μCi ^{3}H-arginine (18 Ci mmol^{-1}). Incubation was at 37 °C for 150 min and the reaction stopped by chilling on ice; the cells were collected and washed once with 5 ml cold phosphate-buffered saline (PBS, 0.14 M NaCl, 2.7 mM KCl, 1.47 mM KH_2PO_4, 8.1 mM Na_2HPO_4), containing 1 mM phenylmethylsulphonylfluoride (PMSF). All subsequent buffers and solutions contained 1 mM PMSF to prevent proteolytic degradation. The cells were resuspended in PBS, PMSF and lysed with 0.15% Kyro EOB (Procter and Gamble). After 10 min at 4 °C no intact cells were detected as judged by Trypan blue staining. The released nuclei were pelleted at 1,000*g* for 15 min and suspended in 20 volumes of 0.15 NaCl, 50 mM Tris-HCl, *p*H 7.5, 1 mM PMSF. The proteins in this nuclear suspension were referred to as total nuclear proteins. The nuclei were pelleted again and washed twice more with 20 volumes of the same solution. At this stage the nuclei could be stored frozen at −20 °C for several days before histone extraction. Histones were extracted from the washed nuclei using 0.125 M H_2SO_4, 1 mM PMSF. Nuclei were suspended in 10 volumes of this solution with a Vortex mixer and left for 1 h in an ice bath with occasional stirring. The suspension was centrifuged for 20 min at 10,000*g* at 4 °C, the supernatant was taken away and the pellet was extracted in the same way once again. The two supernatants were combined and referred to as total histones. Determination of the incorporation of the radioactive amino acids into total nuclear proteins and into histones: aliquots of the nuclear suspension in 0.15 M NaCl, 50 mM Tris-HCl *p*H 7.5, 1 mM PMSF and of the acid extracted histones were precipitated with 20% TCA and were left for 30 min on ice. The protein precipitate was collected on Millipore filters and washed four times with 5 ml cold 12% TCA. The radioactivity on the filters was determined by liquid scintillation counting. *c*, Incorporation of ^{3}H-lysine and ^{3}H-arginine into histone H1 (▼); histones H3, H2a, H2b (■); and histone H4 (○). The histone classes were separated by SDS-polyacrylamide electrophoresis[15], the Coomassie blue stained protein bands cut out, the proteins extracted from the gel slices with 0.5% SDS and the radioactivity in the extracts determined by liquid scintillation counting.

0028-0836/78/0276—0276$01 00

the extent of release of Friend virus sixfold greater than the levels observed in cells in exponential growth phase[12].

General protein synthesis gradually increases during the cell cycle, with the notable exception of histones. Synthesis of histones is restricted to the S phase of the cell cycle and is correlated with the synthesis of DNA[13] suggesting that the chromosome as a whole and not just its genetic material is reproduced during S phase. As *n*-butyrate treatment changes the course of the cell cycle we studied the labelling and appearance of histones in the nuclei during the early stages of the induction period. Figure 1*b* shows synthesis and appearance of histones and of total nuclear proteins in nuclei of *n*-butyrate treated cells. Radioactive labelling was done with ^{3}H-arginine and ^{3}H-lysine for 150 min in conditions where uptake of radioactivity was linear for more than 4 h. The rate of protein synthesis and rate of appearance of proteins in the nucleus steadily decreased during the 48-h period studied. This is similar to the early decrease in total cellular protein synthesis which has been recently reported for Friend cells in which haemoglobin synthesis has been induced by actinomycin D (ref. 14). In contrast to this decrease is the increasing level of newly synthesised histones in the nuclei: an initial period of 4 h with no change is followed by a pronounced increase in the amount of newly synthesised histones to a level two times greater than that in exponentially growing cells. This increase takes place concurrently with a decrease in the rate of DNA synthesis. These data suggest that an uncoupling of histone synthesis and DNA synthesis occurs before haemoglobin is produced. This dissociation represents an early effect after the addition of the inducer and leads to a higher rate of synthesis and transport of histones to the nucleus than in a state of exponential cell proliferation.

To establish whether all histone fractions respond in parallel or whether there is a differential effect in the different histone classes, labelled histones were separated by electrophoresis on SDS-polyacrylamide gels[15]. Histone bands located by Coomassie blue staining were excised and their radioactivity content determined. Separation of histones H3, H2a and H2b was not satisfactory and the three histones were treated as one fraction. The rate of accumulation of newly synthesised histones H1, H4 and (H3+H2a+H2b) is shown in Fig. 1*c*. The rate of appearance of the newly synthesised histones in nuclei is similar for all classes, indicating that the synthesis of nucleosomal histones and the synthesis of histones binding to DNA in the internucleosomal region are regulated coordinately and dissociated from DNA synthesis. This special mode of histone synthesis seems to occur in parallel with hyperacetylation of histones which has been recently described in *n*-butyrate-induced Friend cells[16] and which seems to be due to inhibition of histone deacetylation[17].

The changes in DNA and histone synthesis described here may reflect some intrinsic features of the commitment event. A prolonged G1 phase is characterised by an increase in the rate of appearance of newly synthesised histones in the nuclei. This increase is seen in all histone classes (including $H1_0$ (ref. 18) but not in total nuclear proteins which show a steady decrease in their rate of synthesis. Prolongation of the G1 phase may facilitate the synthesis and modification of regulatory molecules required for the S phase during which reprogramming towards the expression of the differentiated function may take place.

Cell specificity in metabolic activation of aflatoxin B_1 and benzo(*a*)pyrene to mutagens for mammalian cells

ENVIRONMENTAL chemical carcinogens are usually nonreactive and have to be enzymatically activated before they can manifest their biological effects[1–6]. Many cell types, including those used for mutagenesis studies, are not capable of activating such procarcinogens; mutagenesis in these cells has been studied by the addition of an enzymatically active liver subcellular fraction[7–9]. However, these liver subcellular fractions readily activate a wide spectrum of compounds into potent mutagens including those which are not carcinogenic to the liver. In addition subcellular preparations differ from intact cells in the profile of the metabolites[10,11] and DNA adducts[12,13] formed after metabolism of various potent carcinogens such as aflatoxin B_1 (AF), benzo(*a*)pyrene (BP), and 7,12-dimethylbenz(*a*)anthracene. These results suggest that the use of subcellular fractions does not truly simulate the *in vivo* situation and

Table 1 Binding of BP to the DNA of fibroblasts and liver cells

	BP binding (ng bound BP per mg DNA) after treatment with: 1.0 μg ml^{-1}	0.1 μg ml^{-1}
Fibroblasts	8.9 ± 3.6	2.0 ± 0.8
Liver cells	3.2 ± 0.4	1.1 ± 0.2

Binding of BP to cellular DNA was determined 24 h after treatment with BP of 10^7 fibroblasts and 7×10^6 liver cells grown in 10 ml of medium per 100-mm Petri dish; 5–7 Petri dishes were used per data point. For isolation of the DNA-BP products, the treated cells were trypsinised, washed extensively with phosphate-buffered saline (*p*H 7.4), and then lysed in buffer containing 10 mM Tris-EDTA, 100 mM Nacl, and 1% SDS (*p*H 7.4). Lysates were extracted twice with an equal volume of distilled phenol, once with an equal volume of 1 part phenol to 1 part chloroform-isoamyl alcohol (v/v 24:1), and a further three times with chloroform-isoamyl alcohol (24 : 1), resulting in a clear interface. The nucleic acids were precipitated from the aqueous phase with 2.5 volumes of absolute ethanol and centrifuged at 1,000*g* for 10 min at 4° C. The precipitate was dissolved in 0.1 SSC (0.015 M NaCl–0.0015 M sodium citrate), and the RNA was digested with ribonuclease A 50 U ml^{-1} for 40 min at 37° C. Phenol and chloroform extractions were repeated as described above, and the DNA was precipitated with 2.5 volumes of absolute ethanol in the presence of 0.1 M NaCl. The precipitate was dissolved in H_2O, and the DNA was determined quantitatively by absorbance at 260 μm. The ratio A_{260} to A_{280} was 1.95 ± 0.05. The BP bound to DNA was determined by dissolving an aliquot in scintillation solution and counting the samples in a Tri-Carb liquid scintillation spectrometer. Both ^{14}C-labelled BP (62.3 mCi mmol^{-1}) and ^{3}H-labelled BP (4.4 Ci mmol^{-1}) were used in the binding studies. Values means ±s.d. derived from four independent experiments, two with each type of label.

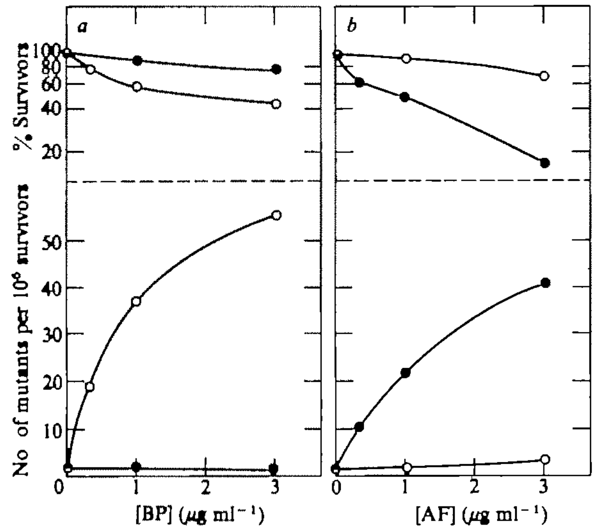

Fig. 1 Fibroblast- and liver cell-mediated mutagenesis by the carcinogens BP (*a*) and AF (*b*). Mutation to ouabain resistance was determined in Chinese hamster V79 cells after co-cultivation with either liver cells or fibroblasts derived from Sprague–Dawley rats. Liver cells were obtained after *in vivo* collagenase perfusion of a liver from a 6- to 10-week-old male rat[18,23]. V79 cells were seeded at 10^5 cells per 25-cm^2 T-flask in 4 ml Williams medium containing 10% fetal calf serum supplemented with 2 mM glutamine, pencillin (100 U ml^{-1}), and streptomycin (100 μg ml^{-1}) at 37° C with an atmosphere of 5% CO_2 in air. After 18 h either 2×10^6 rat embryo fibroblasts (lethally irradiated with 5,000 R) or 10^7 primary rat hepatocytes (80–90% viable by Trypan blue dye exclusion and plating efficiency of 20%) were seeded on the V79 cells. After 3 h the medium was changed and the carcinogens were added in 8 ml of fresh medium. The cells were dispersed 48 h later with 0.05% trypsin and 0.02% EDTA, and the V79 cells, which could be distinguished in the haemocytometer from the fibroblasts and liver cells, were seeded at 200 cells per 50-mm Petri dish in 4 ml medium to determine cloning efficiency and at 10^5 cells per 50-mm Petri dish to determine the number of ouabain-resistant colonies. Ouabain was added 48 h later in 1 ml medium to a final concentration of 1 mM. Six dishes were stained with Giemsa 6–7 d after cell seeding to determine cloning efficiency, and 20 dishes were stained after 14–16 d to determine the number of ouabain-resistant colonies. Data are expressed as the number of ouabain-resistant mutants per 10^6 survivors based on the number of cells seeded for mutant selection and on the cloning efficiency. Data are the results of three separate experiments, and each data point was determined in duplicate. The number of mutants after induction with BP in the fibroblast-mediated assay and AF in the liver-cell-mediated assay varied up to about 25% in the three independent experiments. In all other cases the number of mutants in different experiments varied up to 40%. The cloning efficiency of V79 cells co-cultivated with liver or fibroblast cells was approximately 60%. Cytotoxicity is expressed as % survivors based on a comparison between the cloning efficiency of V79 cells co-cultivated in the absence of carcinogen and that in the presence of the carcinogen. After co-cultivation the number of V79 cells per T flask ranged from 1.2 to 2.8×10^6 cells. The heritability of ouabain resistance was shown with 10 isolated ouabain-resistant colonies, all of which remained resistant to the drug after 1 month in its absence. ●, Liver cells; ○, fibroblasts.

that it may be advantageous to use intact cells for metabolic activation of chemical carcinogens. Therefore, studies of carcinogen metabolism and mutagenic activity in cultured cells derived from different tissues should more truly reflect the *in vivo* situation and should also provide insight into the problem of tissue specificity in chemical carcinogenesis. Metabolic activation by intact cells of different carcinogens into intermediates which are mutagenic to mammalian cells has been reported[4,14–19]. This report compares the abilities of two different cell types, fibroblasts and liver cells derived from rats, to metabolise two carcinogens (BP, a potent skin and lung carcinogen which can also produce fibrosarcomas[20], and AF, a potent liver carcinogen[21]) to water-soluble products, to intermediates which bind to cellular DNA, and to intermediates which are mutagenic to Chinese hamster V79 cells. Ouabain resistance was used as the genetic marker in V79 cells[14,22].

Direct mutagenicity (that not requiring further metabolism of the carcinogens) was determined by testing the induction of ouabain resistance by AF and BP in V79 cells which do not metabolise these carcinogens. The results indicate that neither BP nor AF induced ouabain resistance in V79 cells at concentrations up to 3 μg ml^{-1}. Co-cultivation of the V79 cells with rat fibroblasts which are capable of metabolising BP (fibroblast-mediated assay) or with rat liver cells which metabolise AF (hepatocyte-mediated assay) in the absence of the carcinogens did not alter the mutation frequency. BP in the fibroblast-mediated assay caused 17-, 34-, and 55-fold higher mutation frequencies than the control at 0.3, 1.0 and 3.0 μg ml^{-1}, respectively (Fig. 1*a*), while in the hepatocyte-mediated assay no significant increase was observed in the mutation frequencies at BP doses up to 3 μg ml^{-1}. Treatment of the V79 cells with AF at 0.3, 1.0 or 3.0 μg ml^{-1} in the hepatocyte-mediated assay resulted in 10-, 20- and 40-fold higher mutation frequencies than the control (Fig. 1*b*). In the fibroblast-mediated assay AF caused only a twofold increase at a dose as high as 3 μg ml^{-1}.

The differences observed in the mutagenic activities of BP and AF in the hepatocyte- and fibroblast-mediated assays suggest that these two carcinogens are metabolised differently in each of the two cell types. Therefore the extent of BP and AF metabolism to water-soluble metabolites[11,24] by hepatocytes and fibroblasts was compared. The results indicate that liver cells metabolise both BP and AF to water-soluble products, while fibroblasts metabolise BP but not AF (Figs 2, 3). For both cell types the metabolism of BP to water-soluble products was proportional to the cell number (Fig. 2*a*), the dose of the hydrocarbon (Fig. 2*c*), and the time of incubation up to 48 h (Fig. 2*b*). After 48 h, BP metabolism by liver cells reached a plateau, probably due to cell degeneration, while in the fibroblasts BP metabolism continued for an additional 24 h. The metabolism of AF by liver cells was also proportional to the cell number, the dose of the carcinogen, and the time up to 24 h (Fig. 2*a–c*). The liver cells showed only a limited increase in AF metabolism after 24 h, presumably due to the cytotoxic effects of AF metabolites and degeneration of the hepatocytes in culture. The fibroblasts did not metabolise AF (Fig. 3*a–c*), and this can explain the absence of AF mutagenicity in the fibroblast-mediated assay.

Therefore, even though on a per-cell basis, liver cells were able to metabolise BP to water-soluble products four to five times as effectively as fibroblasts (Fig. 2*a–c*), in the hepatocyte-mediated assay BP was not mutagenic (Fig. 1*a*). These findings raised the question of production and/or release of mutagenic BP metabolites by the liver cells. To estimate the relative production of reactive BP intermediates by the two cell types, the binding of BP metabolites to DNA of both cell types was measured. After 24 h exposure to BP at 1 μg ml^{-1}, approximately three times as much BP was bound to the DNA of the fibroblasts as was bound to the DNA of the liver cells (Table 1). Thus even though the liver cells metabolised four to five times as much BP at 1 μg ml^{-1} to water-soluble products, they had substantially less DNA-bound BP products than the fibroblasts. These findings indicate either that liver cells metabolise BP to less reactive intermediates as compared with fibroblasts, or that if such reactive metabolites are formed they are rapidly detoxified. It has been reported that the degree of covalent binding of BP metabolites to DNA is regulated by their relative rate of production and their rate of detoxification[25].

The mutagenic activity of BP in the fibroblast-mediated assay but not in the hepatocyte-mediated assay and the inverse situation with AF are in agreement with the *in vivo* activities of these two carcinogens. However, 'S-9' subcellular fractions from liver tissue have been reported to activate both carcinogens to

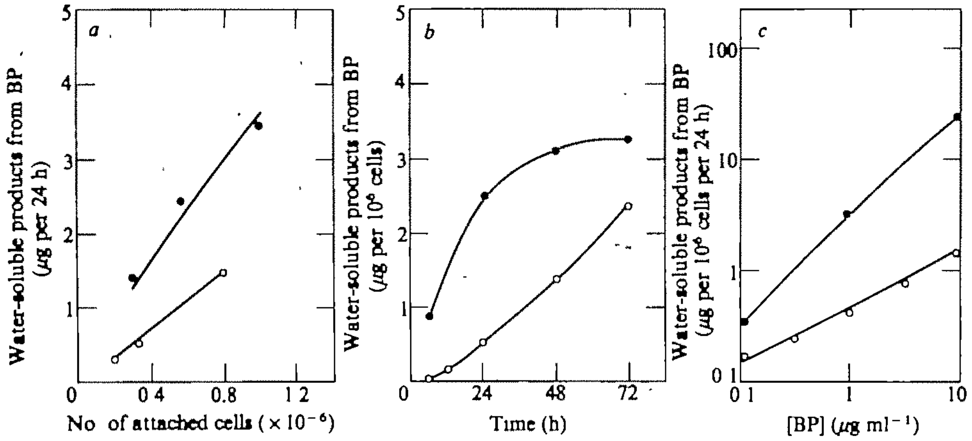

Fig. 2 Metabolism of BP by liver cells and fibroblasts. Liver cells were isolated after *in vivo* collagenase perfusion of the liver of a 6- to 10-week-old male rat, and the cells (viability, 80–90%) were seeded into 25-cm^2 T flasks in 5 ml medium. The plating efficiency was about 20%. Lethally irradiated (5,000 R) rat embryo fibroblasts were seeded in 5 ml of medium into 25-cm^2 T flasks. The plating efficiency of the fibroblasts was about 80%. At 3 h after seeding the medium was changed and 5 ml medium containing the ^{14}C-AF or ^{14}C-BP was added. The reaction was terminated by addition of 5 ml of a 1% SDS solution to each T flask[24]. The contents of the flask were then mixed with a pipette to ensure that all cells lysed, and 5 ml was removed and mixed with nine volumes of chloroform–methanol (2:1). The solution was vigorously mixed and then centrifuged. Duplicate 0.5-ml aliquots of the aqueous (upper) phase were removed and added to 10 ml Aquasol for counting in a Beckman Model B scintillation counter. Total recoveries were 90–100% as determined by summing radioactivities in the aqueous and organic phases. In the absence of cells, 0.3–0.6% of the ^{14}C-BP and 3.0–4.5% of the ^{14}C-AF were soluble in the aqueous phase; this was considered as background. All experiments were run with three dishes per point, and each experiment was repeated 2-3 times. The data presented are the mean values, and the variance between different experiments was up to 15%. Liver cell numbers were determined by counting five different fields of the T flask with a grid. Stock solution of the medium containing a known amount of the radioactive carcinogen AF (2–3 × 10^4 c.p.m. ml^{-1}; [G-^{14}C]AF) or BP (4-5 × 10^4 c.p.m. ml^{-1}, [7,10-^{14}C]BP) with the desired quantities of unlabelled BP or AF was added to each culture. Thus the total radioactivity in an individual experiment remained constant, but the specific activity decreased as the dose increased. ●, Liver cells; ○, fibroblasts.

intermediates which are mutagenic for both *Salmonella typhimurium*[7] and V79 cells[8]. These differences in the metabolic activation may result from the disruption in the liver subcellular preparations of the normal balance of pathways by which BP and AF are activated and detoxified in the intact liver.

Our results indicate that a cell type specificity in chemical carcinogenesis can be investigated by the cell-mediated assay. Furthermore, while the metabolism of procarcinogens is required to manifest *in vitro* mutagenic activity, overall metabolism alone is not sufficient to predict the activity of a carcinogen in a given cell type. The discrepancy between the metabolic activation of the same chemical carcinogens by subcellular fractions as opposed to intact cells and the loss of cell specificity by the former lead us to suggest that the cell-mediated assay may provide a more useful means of screening environmental chemicals and may also be used to study tissue specificity of chemical carcinogens *in vitro*.

Volatile nitrosamines in normal human faeces

NITROSAMINES are a major class of chemical carcinogens which lead to a wide variety of tumours in many animals[1]. They may be formed *in vitro* by nitrosation of primary[2], secondary[3] or tertiary amines[4] and are found in air[5], water[6], foods[7] and consumer products[8]. They may also be formed *in vivo* in the stomach or small intestine of experimental animals following the concurrent administration of nitrite and precursor amines[9–12]. Here we show that several volatile nitrosamines are present in normal human faeces and suggest that they have been produced endogenously in the lower gastrointestinal tract.

Previously, we had used freeze-dried faecal samples for studies of the mutagenic compounds (presumptive carcinogens) in faeces[13]. However, this method does not test for volatile compounds of possible interest. Hence, the freeze-drier condensate was extracted with dichloromethane and this extract was injected on either a gas–liquid chromatograph (GLC) or a high-pressure liquid chromatograph (HPLC), connected to a thermal energy analyser (TEA). Several peaks were observed (Fig. 1) and were attributed to nitroso compounds, as the TEA detector is highly specific for NO-containing compounds. By comparison with standards, the five major peaks were tentatively identified as due to *N*-nitrosodimethylamine (NDMA), *N*-nitrosodiethylamine (NDEA), *N*-nitrosodibutylamine (NDBA), *N*-nitrosopiperidine (NPIP) and *N*-nitrosomorpholine (NMOR), the amounts present in a typical condensate being, respectively, 0.04, 0.10, 0.08, 0.08 and 0.02 μg per l.

The assignment of the TEA peak from the faecal condensate was confirmed by four methods. First, the estimates of the five nitrosamines obtained by either GLC or HPLC were found to agree quantitatively. Second, the isolated fraction corresponding to the peak for NDMA on HPLC was found to give only one peak on GLC–TEA, corresponding to the position of NDMA. The same was true for NDEA, NDBA, NPIP and NMOR.

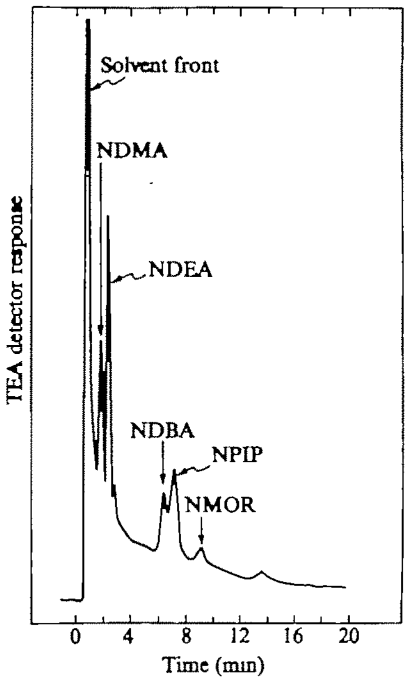

Fig. 1 GLC for a 5-μl DCM extract of the condensate from the freeze drier. 14 feet of stainless steel tubing (outer diameter 1/8th inch), packed with 10% Carbowax 20M on Chromosorb W, 80–100 mesh was used for a single-column isothermal gas chromatograph. The carrier gas was argon at a flow rate of 30 ml min^{-1} and the column oven temperature was 150 °C. A model TEA-502 thermal energy analyser (TEA, Thermo Electron) was used as the detector TEA attenuation was ×8. The last peak on the chromatogram is unidentified.

Third, when the dichloromethane extract of the condensate was treated with HBr in glacial acetic acid it no longer gave any peaks on the TEA detector. The same was true when the extract was transferred into aqueous acid solution and exposed to ultraviolet light. As both these treatments are known to cleave the N–NO bond of nitrosamines[14,15], the peaks seen in Fig. 1 were presumably due to nitrosamines. Fourth, the fractions corresponding to NDBA and NPIP were purified by HPLC after several clean-up procedures[16] and the presence of the compounds in the purified fractions was confirmed by comparing the spectra obtained with mass spectroscopy (GLC–MS) with that obtained with standards for NDBA and NPIP[17]. The finding that faecal distillates contained volatile nitrosamines prompted an extensive investigation of these compounds in normal faeces.

Faecal samples were collected from 12 healthy volunteers at the Ontario Cancer Institute and immediately extracted with

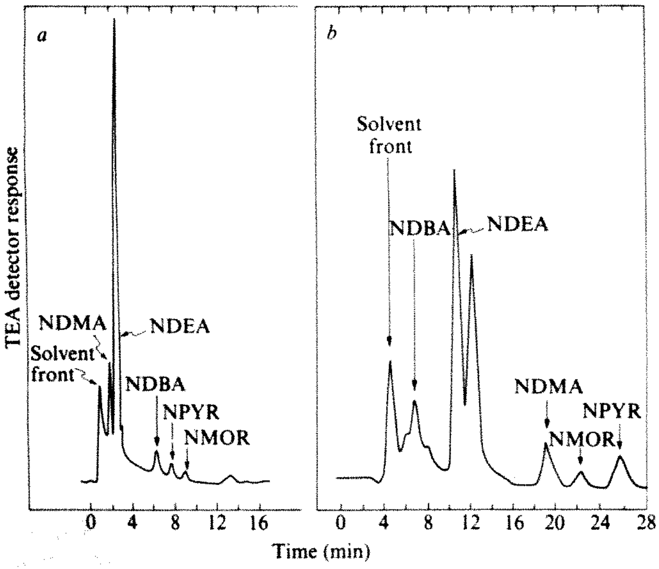

Fig. 2 *a*, GLC for a 10-μl DCM extract of the faecal sample from donor *A*. The operating conditions for GLC–TEA were identical to those described in Fig. 1. *b*, HPLC for a 20-μl DCM extract of the faecal sample from donor *A*. The HPLC–TEA was constructed by connecting a model UK6 injector (Waters Associates) with a model 6000A high-pressure pump solvent delivery system (Waters Associates) and a model TEA-502 thermal energy analyser (Thermo Electron). A μ-porasil column (0.39 cm inner diameter × 30 cm; Waters Associates) was used with a 5% acetone–95% 2, 3, 4-trimethylpentane solvent system at a flow rate of 1 ml min^{-1}. TEA attenuation was ×8. The peak after NDEA on HPLC chromatogram is unidentified.

dichloromethane. The extract was dried with sodium sulphate, concentrated and then distilled from mineral oil to a liquid nitrogen cold trap[18]. The distillate was extracted with dichloromethane and then applied to GLC–TEA or HPLC–TEA in conditions similar to those described by Fine[19]. Control experiments showed that the reagents and chemicals used in the analytical procedure contained no volatile nitrosamines and that the addition of ascorbic acid to the faeces, at a concentration which inhibits nitrosation of amines[20] (1 mg per g of faeces), did not affect the yield. With this method, the recovery of NDMA, NDEA, NDBA, NPIP, NPYR and NMOR at a concentration of 2 μg per kg added to the faeces was found to be 51, 68, 80, 81, 88 and 88%, respectively.

Results of a typical GLC–TEA and HPLC–TEA tracings for the faeces from one volunteer (donor *A*) are shown in Fig. 2. The identification of the peaks as NDMA, NDEA, NDBA, NPYR and NMOR in Fig. 2 was confirmed by the first three methods described above. The results for 12 samples (Table 1) show that most faeces contain NDMA at levels of 0.3–1.5 μg per kg. NDEA was found in higher amounts (0.2–13 μg per kg), with samples from both males and females giving values >10 μg per kg. Two samples had detectable levels of NDBA, in both cases <1 μg per kg. NPYR and NMOR were found in several donors, with detectable levels <2 μg per kg. Many of the levels here are higher than those found in the freeze-dried condensate. Presumably, losses occurred during the freeze-drying period and not all the volatile nitrosamines were retained in the freeze drier.

The source of the nitroso compounds in the faeces has not been established. Perhaps some may arise in food or from nitrosation in the stomach but it seems more likely that they are produced in the lower gastrointestinal tract, as Tannenbaum *et al.*[21] have shown that the nitrite precursor may be present at these sites. It has been suggested that the intestine might be a site for the formation of nitrosamines by bacterial action[22]. The formation of nitrosamines from precursor amines and nitrate at neutral *p*H by some strains of bacteria has been demonstrated by Sander[23] and the formation of *N*-nitrosodimethylamine on incubation of ^{14}C-dimethylamine and sodium nitrite with rat faecal contents has also been reported[24,25]. The levels of volatile nitroso compounds in human faeces are similar to those in some foods[7]. However, the long, continuous exposure to nitroso compounds in faeces could pose a greater hazard than that from many foods. The volatile nitroso compounds present in the faeces will presumably be absorbed and distributed throughout the body. Indeed, the absorption from this site may explain the presence of nitroso compounds in the blood[19] and urine[26] of normal individuals. Although the presence of these nitroso compounds in the human body is surprising, it remains to be determined whether they are responsible for any human cancers.

We thank Dr R. Bonner and Mr D. Robinson of the Laboratory Services Branch, Ministry of the Environment, Toronto, for the GLC–MS analyses. This work was supported by grants from the NCI of Canada and the Ontario Cancer Treatment and Research Foundation.

Tetrahydropapaveroline induces small granular vesicles in brain dopamine fibres

TETRAHYDROISOQUINOLINES (TIQs) can be formed by the condensation of catecholamines with aldehydes. Their *in vivo* formation has been postulated as a possible mechanism to explain some long-term effects of ethanol on the central nervous system[1,2]. However, there have been several criticisms[3,4] and reviews[5,6] of this hypothesis. Although TIQ formation may not explain all the effects of ethanol, TIQs can influence behaviour[7–9] and they do have transmitter-like properties: they can be formed *in vivo*[10–12]; they can be taken up and released *in vivo* from the adrenergic plexus of the rat iris[13]; they can be taken up into rat brain synaptosome fractions[14]; and TIQs applied exogenously have been localised in peripheral catecholamine tissues with both fluorescence[13] and electron microscopy[15]. Thus, TIQs may accumulate in specific brain regions and influence behaviour by either acting as false transmitters[13] or by displacing endogenous transmitters. Critical to this TIQ hypothesis is the demonstration of TIQ uptake and localisation into central neurone terminals. In the present study, slices of rat caudate nucleus were incubated with TIQs and then examined with the electron microscope. The results provide evidence for both the uptake and localisation of the TIQ, tetrahydropapaveroline (THP), into central dopamine fibres and terminals. This localisation may prove important in understanding the mechanism by which TIQs influence animal behaviour and any possible role for TIQs in chronic alcohol consumption.

We used male Sprague-Dawley rats (250–350 g); razor-blade slices of caudate nucleus were incubated for 30 min at 37 °C with various compounds at 5×10^{-4} M (refs 16–18). Tissues were then fixed with potassium permanganate and examined under the electron microscope[19]. After incubation with THP, small granular vesicles (SGVs) were seen in 5-6% of the bouton population (Fig. 1 and Table 1). These SGV boutons were similar in appearance to those identified by others as containing dopamine[16–18,20].

Two further experiments were carried out to determine whether the THP-induced SGV boutons were dopamine terminals. First, as dopamine is actively accumulated[21,22] but does not normally produce a granular precipitate within dopamine-containing synaptic vesicles[16,23], it might block THP uptake and thus the appearance of SGVs in dopamine terminals. Table 1 shows that caudate nucleus incubated with both THP and a 10-fold concentration of dopamine (5×10^{-3} M) was practically devoid of THP-induced SGV boutons. Second, as striatal dopamine innervation is predominantly ipsilateral[20,24], a unilateral lesion of its source nucleus, the substantia nigra, should cause a decrease in dopamine terminals on the lesioned side[20,24]. Table 1 shows that after unilateral 6-hydroxydopamine lesions[20,25] <1% of the boutons contained THP-induced SGVs as compared to 5–6% in the non-lesioned contralateral hemisphere. Substantia nigra lesions were confirmed by both a decreased glyoxylic acid-induced monoamine fluorescence (ref. 26, without perfusion) in the ipsilateral caudate as compared to the non-lesioned contralateral side and a pronounced contralateral asymmetry 10–15 min after a subcutaneous injection of apomorphine (0.25 mg per kg). Although these results are not conclusive, they indicate that THP can be accumulated in central nerve terminals, that these terminals contain dopamine and that they arise from cell bodies in the substantia nigra. Other monoamine terminal regions might also be expected to accumulate THP.

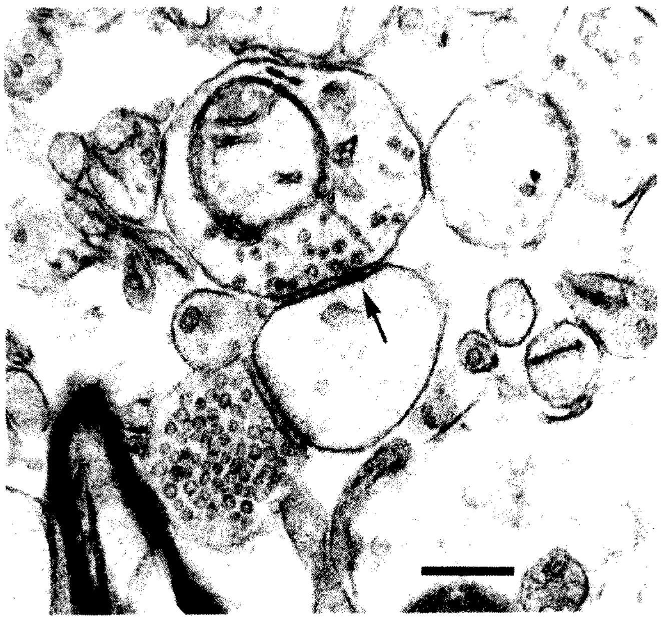
Table 1 Tetrahydropapaveroline-induced small granular vesicle-containing boutons (THP-SGV boutons) in the rat caudate nucleus

	THP-SGV boutons	Total boutons	%THP-SGV boutons
Caudate nucleus from non-lesioned rats			
THP only	497	8,806	5.6
THP + dopamine (5×10^{-3} M)	2	10,391	0.02*
Caudate nucleus after unilateral substantia nigra lesion			
Contralateral to lesion	629	11,761	5.3
Ipsilateral to lesion	48	12,141	0.4*

Slices of rat caudate nucleus were incubated with 5×10^{-4} M THP as outlined in the text. Three unit areas of 6,500 μm^2 from each rat (two rats in each group) were examined.

* $P < 0.001$ (χ^2 test).

Fig. 1 Electron micrograph. The arrow in the dendrite points towards a tetrahydropapaveroline-induced small granular vesicle-containing bouton in the rat caudate nucleus. Note that these granular vesicles are larger in diameter than the agranular vesicles seen in the adjacent bouton. Scale bar, 250 nm.



Our object was in part to identify the THP-induced SGV boutons as either dopamine- or non-dopamine-containing terminals. Thus, the drug concentrations used (5×10^{-4} M) were well above selective uptake levels but were similar to the concentrations used by others to demonstrate dopamine terminals[17,18]. In addition, lower concentrations of THP reveal fewer dopamine terminals[27]. Interestingly, incubation with another dopamine-derived TIQ, salsolinol, and also tetrahydropapaverine, apomorphine and morphine (all at 5×10^{-4} M) failed to produce SGV boutons. Incubation with α-methylnoradrenaline or 5-hydroxydopamine (5×10^{-4} M) revealed SGVs in 10–11% of the striatal bouton population; this is similar to values reported by others[18,20].

Compounds localised within vesicles may or may not produce a granular precipitate after permanganate fixation. The efficiency with which a compound produces a precipitate may be determined by its reactivity towards the permanganate ion, or by its ability to precipitate with manganese dioxide[23]. Thus, the presence of a granular precipitate within vesicles probably indicates uptake, but the absence of precipitate could simply reflect the inefficiency or inability of a compound to sequester the electron-opaque manganese dioxide.

Reports by Myers and co-workers[7–9] have renewed interest in the possible relationship of the TIQs to the physiological processes involved in alcohol addiction. In particular, intraventricular injections of THP were reported to induce rats to consume excess quantities of alcohol voluntarily as compared to control rats[7–9]. It was also reported that another TIQ, salsolinol, and a β-carboline, noreleagnine, caused rats to drink alcohol in excess of controls.

If TIQs are important mediators of the effects of ethanol on the brain, the central catecholamine terminals would provide an opportune target for TIQ formation, storage and release. The present study presents ultrastructural evidence that exogenous TIQ can be accumulated and stored in central dopamine terminals. This cytochemical strategy may prove useful in future efforts to prove or disprove the TIQ hypothesis of alcohol action.

Primary afferent depolarisation of tooth pulp afferents is not affected by naloxone

RECENT studies (for review see ref. 1) have indicated the existence of endogenous opiate-related peptides and opiate receptors in the dorsal horn of the spinal cord and in the trigeminal nucleus caudalis (the caudal-most component of the trigeminal spinal tract nucleus in the brain stem). Both structures have marginal and substantia gelatinosa layers, receive the terminals of Aδ and C nociceptive afferents, and constitute essential components of spinal or trigeminal nociceptive pathways[2,3]. It has been suggested[1,4–7] that endogenous opiate-related peptides located in presynaptic endings play an important part in nociceptive transmission by inhibiting the presynaptic input to neurones in nociceptive pathways; presynaptic inhibition is thought[8] to result from primary afferent depolarisation (PAD). It has previously been found that jaw-opening reflex activity[9–11] and the responses of trigeminal brain stem neurones[10,11] to noxious orofacial stimuli can be suppressed by stimulation of the periaqueductal grey matter (PGM) and that this descending control is at least partially narcotic-related in the cat, as it can often be reversed by administering the opiate antagonist naloxone. Furthermore, the iontophoretic application of the opiate-related peptide enkephalin also depresses the activity of these neurones[12,13]. If the opiate-related peptides are in fact involved in this suppression at a presynaptic level, then by stimulating PGM and related structures one should be able to produce PAD in nociceptive afferents and then abolish the PAD by naloxone administration. We describe here the first test of this proposition, using the tooth pulp (TP) as the source of nociceptive afferents[14,15]. We have found that these afferents are subject to PAD which, however, cannot be abolished by naloxone.

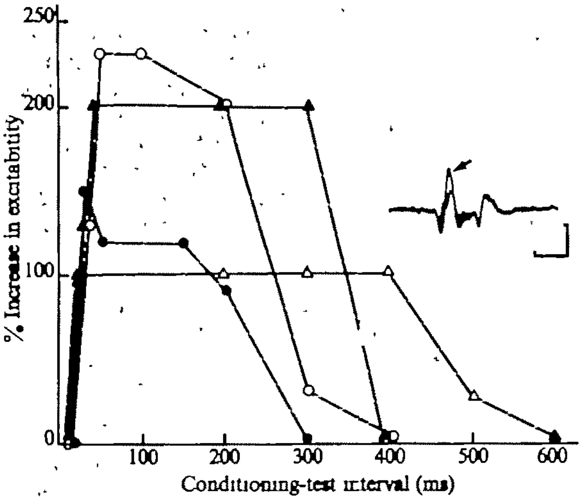

Fig. 1 Increase in antidromic excitability of a single mandibular canine tooth pulp (TP) afferent ending in trigeminal nucleus caudalis produced by conditioning stimulation of PGM (●), NRM (○), maxillary canine TP (▲) and mandibular skin (△). At each conditioning-test interval, the incidence of a spike evoked antidromically by 10 test stimuli to the caudalis was compared with that evoked by a similar number of caudalis stimuli in the presence of a conditioning stimulus. An increase in incidence produced by the conditioning stimulus was expressed as a % increase in antidromic excitability. The insert shows the spike (arrow) evoked antidromically at threshold by one caudalis stimulus, superimposed on a trace where the caudalis stimulus did not elicit the spike although other antidromic activity was evoked Voltage calibration, 0.2 mV; time calibration, 2 ms.

Most of the methods used have been described in detail elsewhere[10,16,17] and will only be briefly described. Thirty cats were anaesthetised with chloralose (60 mg per kg) or decerebrated. Blood pressure, rectal temperature and end-tidal % CO_2 were monitored continuously. In five of these cats, we recorded the activity of single primary afferent units in the trigeminal ganglion that could be orthodromically excited by bipolar stimulation of the ipsilateral canine TP[17] and antidromically activated by brain stem stimulation. In most animals, however, bipolar recordings of TP afferents were actually made from the TP. For such recordings, two drill holes were placed in each of the canine teeth, to a depth at which only a very thin layer of dentine was left, and the TP was carefully exposed by inserting a sharp needle through the thin dentine wall. Bipolar platinum electrodes were implanted in each TP with dental cement. The brain stem was exposed and electrodes located stereotaxically in the trigeminal brain stem nuclei oralis and caudalis, using recordings of maximum field potentials evoked by TP or infraorbital nerve (IO) stimuli, and histological verification. Usually, single-unit activity as well as compound action potentials could be antidromically evoked from TP by stimulation (0.1-ms pulse) of these brain stem nuclei. The rate of brain stem stimulation was limited to 0.5–1 Hz. We noted that at brain stem stimulation rates above 1 Hz, the amplitude of the antidromically evoked compound action potential was enhanced. This would reflect increased excitability and PAD, presumably due to a temporal summation effect induced by preceding brain stem stimuli.

Electrodes were also stereotaxically placed (with histological verification) in the following structures for subsequent conditioning stimulation: PGM, contralateral thalamic nucleus ventralis posteromedialis (VPM), nucleus raphe magnus (NRM) and adjacent reticular formation. Bipolar stimulation of these three sites, plus IO, TP and facial skin, were used as conditioning stimuli (10 ms, 400-Hz train, or 200 ms, 100-Hz train, or single 0.2-ms pulse). Mechanical stimuli applied to the facial skin were

0028-0836/78/0276—0283$01 00

also used, and included an alligator clamp described as noxious when applied to human skin, a brush and an electronically controlled mechanical probe. The presynaptic modulation by these various conditioning stimuli of TP afferents was determined by measuring a change in their antidromic excitability. An increase in amplitude of the antidromically evoked compound action potential or increase in the probability of antidromic activation of single TP units, were used as measures of PAD[8,16,18].

Table 1 Incidence of PAD produced in TP afferent endings in nucleus oralis or nucleus caudalis by various conditioning stimuli

Conditioning stimulus	Oralis	Caudalis
PGM	66% (47)	64% (64)
NRM	83% (18)	73% (37)
VPM	90% (10)	76% (25)
IO	81% (11)	68% (19)
TP	87% (14)	75% (20)

The numbers in parentheses indicate the number of units tested with each conditioning stimulus.

The following criteria were used to distinguish single-unit activity from compound action potentials: the clear and consistent shape of the former, displaying 'all-or-none' firing at its threshold for antidromic activation, with a constant latency and ability to follow high-frequency (100 Hz) stimulation (to exclude the trigeminal tract reflex[19] which we observed occasionally). A total of 150 units were recorded in TP or the trigeminal ganglion. Antidromically induced compound action potentials and single-unit activity had latencies ranging over 2–6 ms, consistent with TP afferents conducting primarily in the $A\delta$ range[14,20].

All the conditioning stimuli used were capable of inducing PAD of TP afferent endings in oralis or caudalis as judged by changes in the antidromic excitability of compound action potentials and single units recorded either in the trigeminal ganglion or ipsilateral TP. There was no selective presynaptic modulation of the small-diameter (TP) afferents by large afferent fibre activation, and our findings of peripherally induced PAD are supported by an earlier report of PAD in TP afferents[20]; however, centrally evoked PAD of TP afferents has not previously been reported (Table 1). Not every stimulation site was effective for every unit, even in the same animal and using the same conditioning and test sites. In general, the incidence of PAD was somewhat lower for endings in caudalis than for those in oralis (Table 1), in agreement with previous reports[16,19] of PAD in trigeminal afferents. The time course of PAD in a TP unit is shown in Fig. 1. PAD was detected at conditioning-test intervals greater than 20–30 ms, was maximal at around 50 ms and lasted for 100–500 ms.

In 22 TP units showing PAD with PGM, NRM or high-intensity skin conditioning stimulation we also tested the effect of naloxone administration (0.4 mg per kg, intravenously); 14 of these 22 units were antidromically excited from caudalis, and eight from oralis. We chose these 22 units for testing because of their consistent and distinctive shape, and the PGM and NRM conditioning stimuli were set at their lowest intensity for producing a reliable PAD effect. Thus, conditions were made as favourable as possible for detecting the reversal of PAD with the opiate antagonist naloxone that would be expected if the presynaptic excitability change induced by these stimuli is related to the action of endogenous opiate-related peptides. The PAD effect was monitored over a period of 25 min after the initial intravenous administration of the drug. Naloxone did not produce any consistent change in baseline antidromic excitability of these units, and only in one of the 22 units tested was there any evidence of a naloxone-induced reduction in PAD. In this unit, the PAD was produced in its oralis endings (antidromic latency 2.3 ms) by both PGM and NRM conditioning stimuli. However, this reduction of PAD as a result of naloxone administration could be overcome by a small increase (90–140 μA) in conditioning stimulus intensity. The effect of naloxone lasted for 15 min, but recurred when a second dose of naloxone (0.4 mg per kg) was given 28 min after the initial administration. No reduction in PAD was noted, however, after naloxone administration in any of the other 21 units; seven of the units were tested with a second dose of naloxone (0.4–2.0 mg per kg, 15-30 min after initial dose), but again no reversal of PAD was noted.

In conclusion, the various conditioning stimuli used were capable of producing PAD in TP afferents. Stimuli to PGM and NRM, sites implicated in several studies[2,21,22] as sources of descending influences related to narcotic analgesia, were very effective in producing PAD. This would suggest that the PAD produced from these sites is related to narcotic analgesia. The opiate antagonist naloxone, however, failed to reverse PAD produced by PGM or NRM (or high-intensity facial) stimulation in 21 of 22 units tested. This may indicate that opiate receptors and opiate-related peptides are not involved in presynaptic modulation of nociceptive input from primary afferents[1,4–7]. However, there are alternative explanations. Our sample of TP units was probably biased towards the large-diameter TP afferents, and although unlikely, it is nevertheless conceivable that the TP units we tested with naloxone may have been involved in functions other than nociception[15]. In addition, although PGM and NRM constitute likely candidates for sites producing modulation, the actual origin of the hypothetical enkephalin terminals on the putative presynaptic opiate receptors is uncertain[2,21,22]. Thus, it is possible that our conditioning stimuli may not have activated a presynaptic enkephalinergic pathway. It is also possible that opiate receptors mediate presynaptic inhibition by some process other than PAD[8].

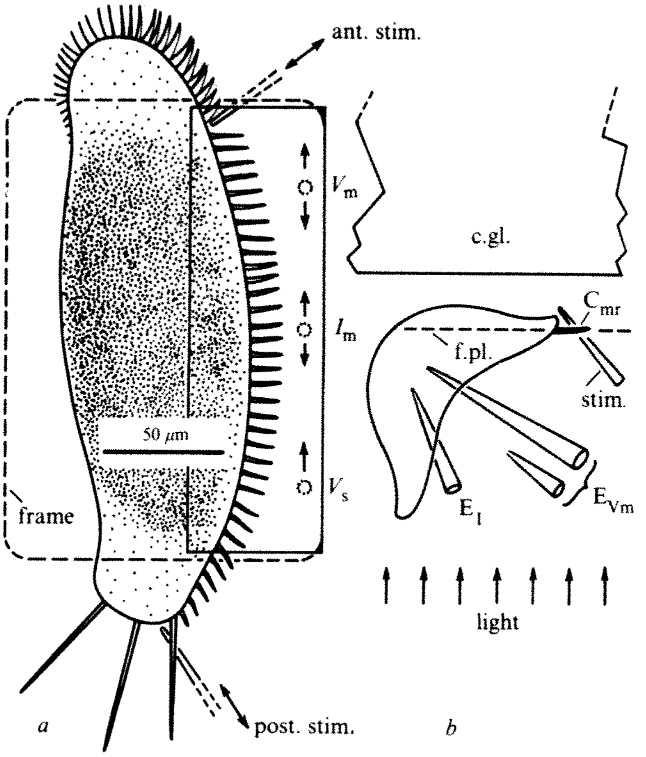
Are receptor-activated ciliary motor responses mediated through voltage or current?

THE locomotion of ciliate protozoa is effected by cilia which modify the direction and frequency of their cyclic beating in response to sensory input from the environment[1,2]. In *Paramecium* and *Stylonychia* mechanical stimulation of the anterior end of the cell induces a Ca^{2+}-dependent depolarising receptor potential which triggers a regenerative Ca^{2+} response[3,4]. Ca^{2+} accumulating in the ciliary space activates the axonemal motor system[5] so that the normal (posterior) direction of the ciliary power stroke is reversed and the frequency is augmented[6]. Posterior mechanical stimulation of the cell elicits a K^+-dependent hyperpolarising receptor potential followed by augmentation of ciliary frequency without reversal[4,7], a mechanism which is less well understood[8]. Because shifts in voltage are associated with loops of electric currents across the membrane, we have examined the crucial signals transmitted from the mechanoreceptive regions to the cilia. We report here that these signals are potentials of either polarity. This is the first report of intracellularly recorded receptor currents.

Fig. 1 *Stylonychia mytilus*, as orientated in the experimental set-up for cinematographic (16 mm, 250 f.p.s.) and electrophysiological recording. *a*, Cell in oblique dorsal view with right marginal cirri (C_{mr}) focused under a compound microscope (Zeiss interference contrast). Vertical oscilloscope deflections of membrane potential (V_m), membrane current (I_m) and driving voltage of piezoelectric stimulator (V_s) optically superimposed on frame. Positions of glass rod for anterior and posterior mechanical stimulation (ant. stim., post. stim.) are indicated. The rectangle marks the outline of photographs in Figs 2–4. Bar, 50 µm. *b*, Position of cell under a cover glass (c.gl.) in the experimental chamber. Electrodes for current passing (E_I) and recording of the membrane voltage (E_{Vm}) were bent to be inserted from below. The position of the glass rod (stim.) was approximately 3 µm from the cell margin before a mechanical stimulus. Experiments were carried out at 18° C.



Single specimens of the freshwater ciliate *Stylonychia mytilus* were mounted on glass microelectrodes (1 M KCl, 40–60 MΩ) under a compound microscope in a solution of 1 mM $CaCl_2$, 1 mM KCl and 1 mM Tris-HCl at *p*H 7.3, to register the stimulus-dependent electrical events as well as the movements of the cirri (Fig. 1). The marginal cirri (10–20 individual cilia, 15–20 µm long) are largely inactivated during the resting state of the cell which occurs while *Stylonychia* 'sits' on substrate surfaces, whereas other compound cilia (membranelles) beat rapidly to produce a feeding water current. Activation of the marginal and ventral cirri produces forward and backward 'walking' locomotion[9]. The experimental cells assumed a steady resting stage 2 min after fixation by two intracellular electrodes (Figs 2–4, leftmost frames) with a resting potential of −51 ± 3 mV.

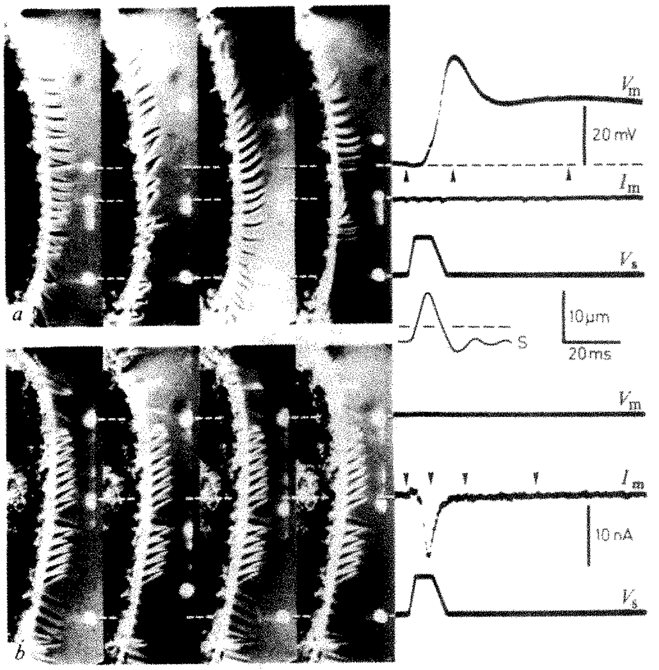


Fig. 2 Electrical and ciliary motor responses to mechanical stimulation of the anterior end of the cell. *a*, Sequence of frames (from left to right) to illustrate the onset of beating of the cirri towards the cell anterior following application of the mechanical stimulus. Oscilloscope traces (right) are graphically joined to signals on photographs (left). Arrowheads mark occurrence of represented frames (4th frame, 140 ms after start of stimulus). Actual tip excursion of needle (S) is indicated below trace of driving voltage (V_s); dashed line limits dead space between resting needle and cell surface[4]. Note activation of cirri during the rising slope of the action potential which rides on top of a receptor depolarisation. Artefacts on current trace (I_m) were picked up from flashes for film exposure. *b*, Absence of motor responses of the cirri after the same mechanical stimulus during voltage clamp of the resting potential. Current trace shows inward receptor current. Conventional oscilloscope display in *b* was recorded directly after filmed sequence to remove amplified flash artefacts from the current trace.

Mechanical stimuli applied to the anterior membrane by the tip of a fine glass rod induced a ciliary motor response within 6–9 ms, coincident with the rising slope of a membrane depolarisation. This electrical response had an early receptor component followed by an action potential[10] (Fig. 2*a*). The activated cirri swung anteriorly to perform several vigorous beating cycles (up to 60 Hz) with the power strokes orientated anteriorly. There was no activation of the cirri when the cell was similarly stimulated while the membrane voltage was clamped to the resting potential by negative feedback to remove the voltage signal (Fig. 2*b*). In this case the anterior mechanical stimulus produced an inward membrane current which rose to a peak (up to 10 nA) within 5 ms and decayed with a time constant of 3 ms, a fraction of the time constant of the decaying depolarising

0028–0836/78/0276—0285$01.00

receptor potential reported elsewhere[4]. The result suggests that a depolarising receptor potential from a brief conductance increase of the anterior receptor channel passively invades the cilia[11] to activate the voltage-sensitive channel of the ciliary membrane[12,13].

Mechanical stimulation of the cell posterior elicited a ciliary motor response (up to 45 Hz) within 10–13 ms together with a hyperpolarising receptor potential (Fig. 3*a*, 11 ms risetime to 26 mV amplitude, 35 ms time constant of decay). In contrast to the effects of depolarising stimuli, the first (Fig. 3*a*, 2nd frame from left) and subsequent ciliary power strokes were directed towards the posterior end of the cell. On the other hand, on stimulation with the membrane potential clamped to its resting value, the cirri remained unaffected, while a strong outward receptor current (Fig. 3*b*, 10 nA, 5 ms risetime, 7 ms time constant of decay) was recorded. The data shown in Figs 2 and 3 suggest that the ciliary apparatus can specifically respond to receptor-dependent depolarisation or hyperpolarisation, but not to the ionic currents accompanying receptor-site activation.

Motor effects of three types of inward membrane currents of similar amplitudes were examined to test the latter hypothesis.

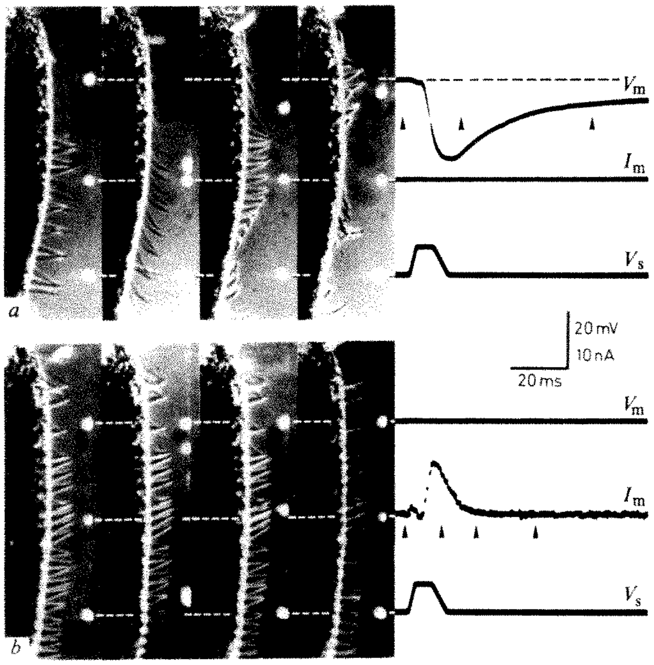

Fig. 3 Effects of posterior mechanical stimulation. *a*, Resting cirri (frame at left) start beating towards the rear of the cell after the occurrence of a hyperpolarising receptor potential (4th frame, 236 ms after stimulus onset). *b*, With the membrane voltage clamped at the resting potential, the same mechanical stimulus gives rise to an outward receptor current (I_m), but the compound cilia remain in the pre-stimulus resting position.

Although an inward receptor current could not activate the cirri in the absence of membrane voltage displacement (Fig. 2*b*), the early inward current due to a depolarising voltage step was accompanied by a reversal response of the cirri (Fig. 4*a*). Inward current from a hyperpolarising voltage step occurred in conjunction with ciliary activation towards the posterior of the cell (Fig. 4*b*). Comparison of Figs 2–4 unequivocally confirms signal transmission to the cilia by means of changes in voltage, not membrane currents. The failure of an inward receptor current to activate the cilia is interesting, as this current is carried by calcium. Estimates of the total ciliary fluid space and the somatic volume (3×10^{-9} cm^3, 4×10^{-7} cm^3; H.M., unpublished), show that a receptor current of 10 nA restricted to the cilia increases the intraciliary Ca^{2+} concentration beyond 10^{-4} M, and raises the internal concentration by 3×10^{-6} M, if Ca^{2+} is evenly distributed in the total cellular space. Both concentrations are sufficient for ciliary reversal[5,14]. Thus, we suggest that Ca^{2+}-receptor channels in *Stylonychia* occur exclusively on non-ciliary membranes. A K^+-dependent hyperpolarising mechanoreceptor channel was also localised on the somatic surface in deciliated *Paramecium*[13], whereas membrane mutants of *P. caudatum* which fail to produce membrane electrogenesis and ciliary reversal[15] exhibit both types of receptor potentials on mechanostimulation[16]. Studies in wild-type *P. caudatum* (A. Ogura and H.M., unpublished) establish inward and outward mechanoreceptor currents and suggest that these currents are absent from the ciliary surfaces.

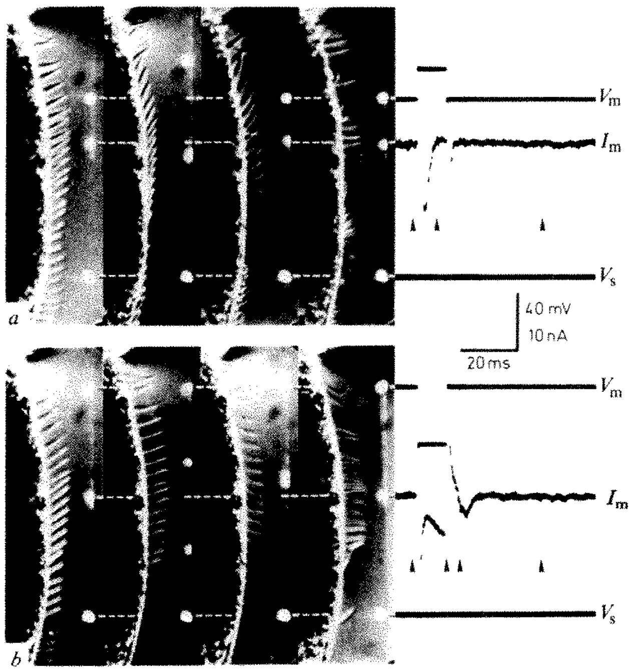

Fig. 4 A test of the adequacy of electrical signal for ciliary activation. *a*, A depolarising voltage step (V_m) produces an early inward current (I_m) and causes the cirri to beat towards the cell anterior (4th frame, 158 ms after voltage stimulus). *b*, A hyperpolarising voltage step accompanied by 'late inward' current activates cyclic beating of the cirri towards the posterior end of the cell. Note that the polarity of the voltage signal determines the ciliary response; the polarity and the size of the membrane current, which is similar to that in Fig. 2*b* (no ciliary activation), is not a signal recognised by the cilia.

We conclude that activation of the ciliary motor response through mechanical stimuli involves the following steps: (1) increase in conductance of the somatic sensory channel; (2) passive spread of the receptor potential into the cilium; (3) conductance modification of the voltage-sensitive Ca^{2+} channel; (4) change in intraciliary Ca^{2+} concentration; (5) Ca^{2+}-dependent activation of the ciliary axoneme.

Site of 1,25(OH)$_2$ vitamin D$_3$ synthesis in the kidney

FRASER AND KODICEK[1] have reported, and others hae confirmed[2–4], that the kidney is the exclusive site of synthesis of 1,25-dihydroxycholecalciferol (1,25(OH)$_2$D$_3$). The 1-α-hydroxylation of 25-hydroxycholecalciferol (25-OH-D$_3$) occurs in mitochondria[1,4,5] and is influenced by cytosol[6,7], although conflicting data have been reported[8]. Preparations of whole tubules from the cortex possess 1-α-hydroxylase activity[10] but the precise localisation of the enzyme along the nephron is not known. In the dog, no evidence of 1-α-hydroxylase was found in medulla, enzymatic activity being observed only in cortical preparations[5]. In mice given systemic injections of ^{3}H-vitamin D$_3$ autoradiography shows the tracer to be present in the proximal tubules[9]. However, whether hydroxylation occurred at this site was not established. Using single nephron preparations, we have now demonstrated that the major and probably exclusive site of synthesis of 1,25(OH)$_2$D$_3$ is the proximal tubule.

One-day-old white Leghorn cockerels were raised in the dark on a rachitogenic, vitamin D-deficient diet (ICN) containing 1.74% Ca and 1.24% inorganic phosphate (P$_i$). Controls of the same strain were maintained on a normal diet, in daylight. Rachitic chickens were distinguished from controls by their stunted growth, their weakness and the paucity of their feathers. Tubules were prepared by a modified technique of Imbert[11]. After an intravenous injection of heparin, 42 64-day-old animals were bled, and the renal arteries were perfused via the aorta with a cold solution of collagenase (1 mg ml^{-1}) in modified Hank's solution containing 1.0 mM Ca. When completely blanched, the left kidney was removed. Thin sagittal slices were cut, from which minute fragments of tissue (0.5 × 0.5 × 3 mm), involving both superficial and deep parts of the kidney, were isolated and digested in collagenase solution (Type 1 from *Clostridium histolyticum*, Sigma) for 1 h at room temperature. Tubules were dissected at 0 °C, in Hank's modified solution.

The kidney of the chicken consists of three lobes, each divided into numerous lobuli. Each lobulus consists of a cortical part (under the kidney surface) containing nephrons which lack loops of Henle, and a medullary part containing nephrons which have short or long loops of Henle. A superficial nephron consists of a glomerulus, proximal tubule and distal tubule connected to the cortical collecting tubule[12–15]. The early part of the proximal tubule (PCT), is convoluted, thick and relatively friable after digestion with collagenase. The PCT continues with a series of parallel hairpin loops, initially thick (thick loop cortex), and later thin (thin loop cortex), which finally connect to the branched collecting tubule (collecting cortex) through a thin distal convoluted tubule (DCT). The division between the DCT and the collecting cortex was difficult to distinguish so these two segments were dissected and tested together. Medullary nephrons were less readily digested by collagenase, and could be dissected as successfully as those of the cortex. Only small bundles of terminal collecting tubules in medulla were isolated satisfactorily. because of the resemblance of these terminal collecting tubules with the papilla in mammals, these structures were classified as papillary collecting tubules (collecting papilla).

After dissection, fragments of individual tubules were grouped according to their morphological characteristics until a total length of 4–16 mm per group was accumulated. Each group of tubules was kept at 0 °C in a drop of modified Hank's solution containing 0.25 mM of Ca, in the depression of a bacteriology slide. Tubules were photographed to measure their length and incubated in 0.6 to 1.0 µl of incubation medium (IM) for 60 min at 35 °C. The final composition of the incubation medium was: malate 10 mM, Tris-HCl 100 mM, MgCl$_2$ 4 mM, EDTA 0.25 mM, glucose-6-phosphate 5 mM, NADP 0.33 mM, glucose-6-phosphate dehydrogenase 600 units l^{-1}, bovine serum albumin 1%. 25-Hydroxy-(26,(27)-methyl^{3}H)-cholecalciferol (^{3}H-25-OH-D$_3$, Roche), 95–110 Ci mmol^{-1} was added to the preparation (the organic solvent for the labelled compound was evaporated under nitrogen previously). The 25-OH-D$_3$ concentration in the incubation medium varied from 135 to 560 nmol l^{-1}. After incubation, the contents of the slide depression were transferred to chromatography paper impregnated with silica gel (Whatman SG 81) and dried under nitrogen. The slide depressions were rinsed 4 times with 5 µl of chloroform–methanol (1 : 2) and the washings were also transferred to the chromatography paper and dried. The chromatograms were developed in the dark for 16–18 h using chloroform–ethylacetate–benzene (40 : 50 : 10) according to the method of Bikle and Rasmussen[10]. They were then dried in air, cut into 2-cm^2

pieces, and dispersed directly into scintillation vials containing 15 ml of toluene based scintillation fluid. The amount of vitamin D metabolites was expressed in fmol based on the original specific activity of the ^3H-25-OH-D_3. Approximately 50% of the total radioactivity was recovered.

The chromatographic properties of the vitamin D metabolites were established using labelled authentic compounds: mean mobility of $1,25(OH)_2$-D_3/25-OH-D_3 ratio was 0.50 ± 0.008 (s.e.m.). In six experiments with rachitic chickens, 10 μg each of carrier 25-OH-D_3 and $1,25(OH)_2$-D_3 were cochromatographed with the proximal tubule preparation, after incubation with ^3H-25-OH-D_3. Unlabelled metabolites were localised on the chromatogram either by spraying with a solution of 10% phosphomolybdate in ethanol or by exposure to iodine vapour; the radioactive metabolites were then localised as previously described. The chromatographic properties of the authentic carrier sterols and the labelled metabolites formed by the tubules were identical (Fig. 1).

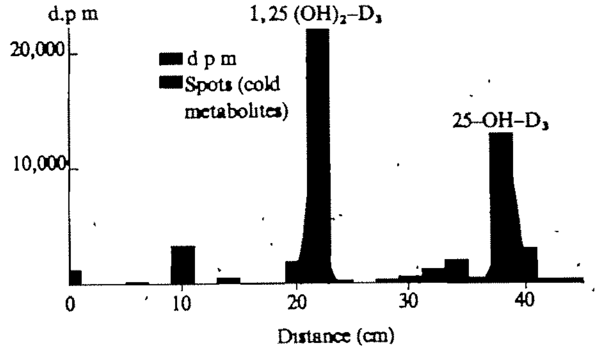

Fig. 1. Cochromatogram of a PCT preparation from a rachitic chicken after incubation with ^3H-25-OH-D_3, and a mixture of the two unlabelled vitamin D_3 metabolites. 25-OH-D_3 and $1,25(OH)_2$-D_3. The labelled metabolite produced by the tubular preparation exhibits identical migration characteristics to $1,25(OH)_2D_3$.

The mean protein content of the tubules was determined in three 10-week-old normal chickens, three 4-week-old normal chickens, and three 7-week-old rachitic chickens. Protein content was measured by a microtechnique described by Butcher and Lowry[16]. Fragments of tubules were processed and photographed as described above. As the protein contents of proximal convoluted tubules and thick loops of the cortex were similar, the results were pooled. Similarly, thin loops of the cortex, distal convoluted tubule, and cortical collecting tubules were combined and assayed together. Protein digestion in tubular preparations and in standards of bovine serum albumin was performed in 1 μl 6 M HCl, under oil, at 120 °C for 4 h. Fluorescence was developed by mixing the digested proteins with 100 μl of a mixture of 1 mM orthophthalaldehyde and 2 mM β-mercaptoethanol in 100 mM sodium tetraborate buffer at *p*H 10. The degree of fluorescence was measured after dilution in 500 μl of 0.5 M NaOH, using an Aminco-Bowman microfluorometer.

Plasma Ca and P_i were 3.33 ± 0.19 mEq l^{-1} and 1.55 ± 0.24 mmol l^{-1} respectively in rachitic chickens, compared to 4.07 ± 1.03 mEq l^{-1} and 2.61 ± 0.30 mmol l^{-1} in controls. The protein content of proximal (PCT thick loops cortex) and distal (thin loops cortex, collecting cortex) segments of the nephron were (μg mm^{-1}) 0.23 ± 0.4 and 0.11 ± 0.00 in 10-week-old chickens, 0.13 ± 0.00 and 0.06 ± 0.005 in 4-week-old chickens, 0.14 ± 0.01 and 0.06 ± 0.01 in rachitic chickens who were 5- to 9-weeks-old. Because of their size, 4-week-old chickens were used as controls, and the values of $1,25(OH)_2$-D_3 produced per mm tubule were converted, in the two series of animals, to fmol per μg of protein, utilising the corresponding tubular protein content.

The levels of 1-α-hydroxylase activity within the nephron segments are given in Table 1 and Fig. 2. The only significant production of $1,25(OH)_2$-D_3 occurred in the PCT and the thick loops of the cortex, in rachitic chickens: 18.1 ± 2.0 fmol and 12.8 ± 3.1 fmol respectively, that is, 1.76 ± 0.19 and 1.73 ± 0.33 fmol per mm of tubular length, or 12.3 ± 1.3 and 12.4 ± 2.4 fmol per μg-protein. No $1,25(OH)_2$-D_3 was produced in the remaining nephron segments. The degree of 25-OH-D_3 transformation to $1,25(OH)_2$-D_3 varied between animals. The mean percentage transformation was 21.0 ± 2.3% and 14.3 ± 2.9% in PCT and the thick loops of cortex, with a maximum of conversion of 53%.

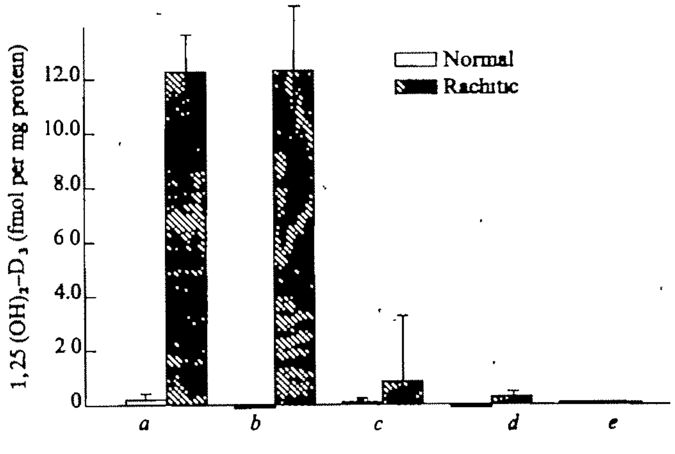
These studies demonstrate that, in vitamin D-deficient chickens, renal 1-α-hydroxylase activity is found exclusively in the proximal tubule. The absence of enzyme activity in the rest of the nephron may be assumed, unless other active segments are too short to produce detectable amounts of enzyme activity with this technique. If a distal site of enzyme activity exists, its activity is negligible in comparison with that found in the proximal tubule.

Our results agree with those reported by Midgett *et al.*[5] who observed 1-α-hydroxylase activity in the cortex of the canine kidney but none in the medulla. In addition, the present data localises the site of the enzyme activity in the cortex, providing evidence that the enzyme is located exclusively in the proximal tubule.

Using homogenates of chicken kidney cortex, Midgett[5] has reported a production of 10 pmol of $1,25(OH)_2$-D_3 per mg of protein after 2 h of incubation. Henry *et al.*[17] using kidney homogenates has reported a production of approximately 1 pmol of $1,25(OH)_2$-D_3 per min per mg of protein. In the present study the proximal tubule exhibited a wide range of enzyme activity depending on age and on various other factors. The mean production of $1,25(OH)_2$-D_3 was 12.3 fmol per μg of protein during a 60-min incubation, a value which is of the same order of magnitude as those found in other laboratories.

The proximal tubule is responsible for most of the P_i reabsorption. In this segment, PTH[18], and in some species, calcitonin[19], stimulate cyclic AMP synthesis which interferes with P_i transport. PTH and cyclic AMP enhance the synthesis of $1,25(OH)_2$-D_3 (refs 20–23) and, conversely, vitamin D and its metabolites increase P_i reabsorption[24–26], probably by interfering with adenyl cyclase activity[27]. The localisation of 1-α-hydroxylase activity within the proximal tubule where the above factors converge their influence, would suggest that $1,25(OH)_2$-D_3 may participate in the regulation of tubular P_i transport.

Fig. 2 $1,25(OH)_2D_3$ synthesised by various segments of the nephron of normal and rachitic chickens. Columns indicate the mean values and bars the standard errors. A significant amount of the vitamin D_3 metabolite was found only in PCT and thick loops of the rachitic chickens. The results are expressed in fmol of $1,25(OH)_2D_3$ per μg of tubular protein. *a*, PCT; *b*, thick loop cortex; *c*, thin loop cortex; *d*, DCT; *e*, collecting papilla.



We thank Dr Uskokovic (Hoffman La Roche) for tritiated sterols and Dr J. Babcock (Upjohn) for unlabelled 25-OH-D_3. We also thank Daniele Chabardes for useful suggestions and L. Camarra and R. Seguin for clerical assistance.

Rapid transbilayer diffusion of 1,2-diacylglycerol and its relevance to control of membrane curvature

SHEETZ AND SINGER have proposed that the actions of certain amphipathic drugs in producing curvature of the membrane of human red blood cells (RBCs) could be explained by assuming that these drugs selectively entered one of the leaflets of the lipid bilayer, thus causing lateral expansion of that leaflet relative to the other[1]. The membrane was therefore forced to curve in order to accommodate this extra material and the direction of this curvature was predictable, leading to production of either stomatocytes or echinocytes. Membrane curvature, leading to the formation of stomatocytes or echinocytes, can also be produced by subjecting human RBCs to phospholipase C attack[2–5]. In this report we attempt to explain these phospholipase C-induced changes in terms of Sheetz and Singer's model, taking into account the observation that 1,2-diacylglycerol (the product of phospholipase C action), unlike phospholipids, can migrate rapidly across the membrane bilayer. Rapid transbilayer migration of 1, 2-diacylglycerol has previously been inferred from the observed increase in the rate of synthesis of phosphatidate in intact RBCs that have been exposed to phospholipase C: this phosphatidate is formed from diacylglycerol and cytosolic ATP by diacylglycerol kinase, presumably at the inner surface of the membrane[2]. We have now used this procedure, in which the endogenous diacylglycerol kinase of the erythrocyte is used to trap 1, 2-diacylglycerol appearing on the inner surface of the red cell membrane, to compare the time courses of phospholipase C-catalysed production of diacylglycerol and of the appearance of phosphatidate, and thus obtain an estimate of the rate of transbilayer migration of 1, 2-diacylglycerol.

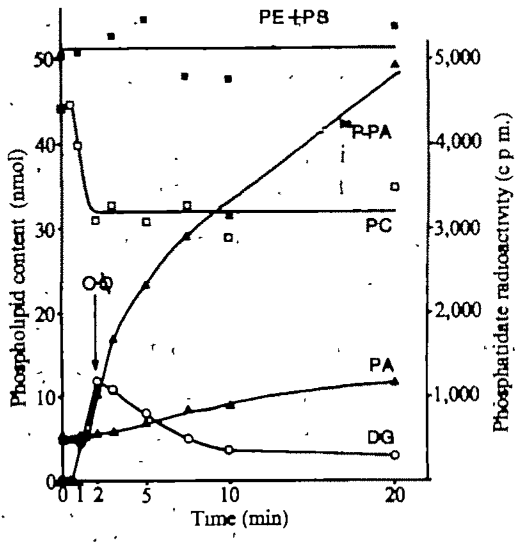

Fig. 1 Time course of production of 1,2-diacylglycerol and phosphatidate in human RBCs exposed to phospholipase C. Outdated human RBCs were washed and prelabelled for 90 min at 37 °C with ^{32}P-Pi (10 μCi ml^{-1}) at a cell concentration of 2×10^9 ml^{-1} in a HEPES-buffered Ringer solution as described previously[2]. Phospholipase C (*C. Welchii* freeze-dried culture filtrate type A, batch AD1051A, Wellcome, Beckenham, UK) was added at a final concentration of 10 μg ml^{-1} and was inactivated after 2 min incubation by addition of *o*-phenanthroline to 1 mM final concentration; 0.5-ml samples of the incubation were taken at various times and immediately added to 1.9 ml of methanol: chloroform: concentrated HCl 200:100 1. Lipids were extracted as described previously and after concentration were separated according to the procedures of Skipski *et al.*[12] (phospholipids) and Freeman and West[13] (neutral lipids). Phospholipids were quantified by the procedure of Bartlett[14] following digestion with perchloric acid, and ^{32}P radioactivity in phosphatidate was measured by Čerenkov counting in a Searle liquid scintillation counter. The 1,2-diacylglycerol spots from the chromatogram were excised and heated at 100 °C for 1 h with 1 ml of methanol: concentrated HCl (10:1) under nitrogen in a screw-top tube. After cooling, the samples were dried at 40 °C under reduced pressure. The residue, which contained free glycerol, was silylated under N_2 at 100 °C for 10 min with a mixture of 20 μl pyridine and 20 μl *bis* (trimethylsilyl)-acetamide (Supelco, Bellefonte, Pennsylvania), 5 μl of the resulting mixture was applied to a 1 5-m GLC column (3% OV1 on 80–100 mesh Supelcoport) at an N_2 flow rate of 40 ml min^{-1} and a temperature of 120 °C in a Pye 204 chromatograph. The silylated derivative of glycerol gave a peak at 3.8 min and was quantified by measurement of peak area compared with peaks given by various amounts of standard dipalmitin (Sigma) which had been treated in an identical fashion. Cell lysis was measured in samples of cells that were taken at various times and diluted in an isotonic saline solution containing 1% formaldehyde (to fix the cells) and 1 mM *o*-phenanthroline which inhibits the phospholipase). The cells were spun down and the optical density at 410 μm of a suitable dilution of the supernate was measured. The experiment shown was one of five which gave closely similar results. ■, Phosphatidylethanolamine + phosphatidylserine, □, phosphatidylcholine; ○, 1,2-diacylglycerol; △, phosphatidate; ▲, phosphatidate radioactivity.

Washed human RBCs were incubated with ^{32}P-phosphate to prelabel their ATP pool. They were exposed briefly to phospholipase C and the enzyme was then inactivated with *o*-phenanthroline (see Fig. 1). Samples were taken at various times and determinations made of 1,2-diacylglycerol, phosphatidate and phosphatidylcholine content. Radioactivity in phosphatidate was also measured.

As shown in Fig. 1, there was a lag of about 30 s before the phospholipase began to attack the RBC lipids rapidly. Breakdown of phosphatidylcholine and accumulation of 1,2-diacylglycerol then continued until the enzyme was inactivated with *o*-phenanthroline at 2 min. The maximal rate of phosphatidate synthesis was about 1.5–2.0 nmol min^{-1} 10^{-9} cells, and this corresponded to the maximum rate observed in other experiments when diacylglycerol kinase was assayed in lysed cells (unpublished) or in membranes[6]. In the experiment in Fig. 1, cell lysis was $<5\%$ in phospholipase-treated cells after 20 min, so that the great bulk of the 1,2-diacylglycerol must have initially been derived from outer-leaflet phosphatidylcholine and must then have traversed the membrane to gain access to diacylglycerol kinase and ATP. This assumption is supported by fatty acid determinations (unpublished) which showed that the compositions of 1,2-diacylglycerol and of phosphatidate derived from it, were not distinguishable from the composition of phosphatidylcholine. The maximum rate of synthesis of phosphatidate was observed about 1 min after achievement of the maximal rate of production of 1,2-diacylglycerol, suggesting that 1,2-diacylglycerol diffused into the inner leaflet of the cell membrane within about 1 min of its production in the outer leaflet. This rate is very much faster than the rates of transbilayer diffusion for erythrocyte phosphatidylcholine, the half-time of which for 'flip-flop' has been estimated as between 0.5 and 6.5 h (refs 7–9).

A schematic diagram to illustrate the possible morphological consequences of this fast diffusion of diacylglycerol is shown in Fig. 2. Formation of diacylglycerol from phospholipid in the outer leaflet (Fig. 2*b*) is followed by rapid movement of diacylglycerol into the inner leaflet (Fig. 2*c*), thus causing a simultaneous contraction of the outer leaflet and expansion of the inner leaflet and a resulting tendency for the membrane to curve inwards. Phosphorylation of the internal 1,2-diacylglycerol (Fig. 2*d*) may further expand the inner leaflet as the utilisation of the diacylglycerol of the inner leaflet would favour the continued diffusion of diacylglycerol in from the outer leaflet. Also as phosphatidate would probably occupy a larger area than 1,2-diacylglycerol. However, the phosphorylation of diacylglycerol should not be the essential step in the induction of membrane curvature; it should be sufficient that phospholipid is broken down on one side of the membrane to give an accumulation of a rapidly migrating species such as diacylglycerol. This model therefore provides a rationale for the membrane invagination which follows attack on RBCs by externally added phospholipase C (ref. 2) and also for the evagination of membrane which follows activation by Ca^{2+} of the endogenous phospholipase C that attacks the polyphosphoinositide of the inner leaflet to give an accumulation of 1,2-diacylglycerol[3–5].

Fig. 2 Membrane bending induced by conversion of phospholipid to 1,2-diacylglycerol in one leaflet of a lipid bilayer, followed by diffusion of diacylglycerol into the other leaflet. *a*, Untreated bilayer; *b*, bilayer treated with phospholipase C on the outside; *c*, equilibration of diacylglycerol across the bilayer with consequent induction of bilayer curvature; *d*, phosphorylation of diacylglycerol to form phosphatidate on the inner face of the bilayer.

In both of these situations, the membrane curvature induced by asymmetric modification of the lipid bilayer brings membrane surfaces closer together and thus is an essential step which precedes the membrane fusion events which cause the release, either internally or externally, of membrane vesicles. As has been suggested before[4], diacylglycerol-rich areas of membrane may promote the membrane fusion process, perhaps by formation of hydrophobic regions segregated from the bilayer[10].

Although this model for the induction of membrane curvature by the unilateral conversion of phospholipids to diacylglycerol applies to the erythrocytes of man and some other species[2–5], similar principles might govern the control of membrane curvature and fusion in other physiological systems. The phospholipases C which have been identified in animal cells are activated by Ca^{2+} and act specifically on phosphoinositides[3,11], suggesting that inositol lipids, and the phospholipases C that attack them, may have an important role in the control of membrane curvature and fusion *in vivo*, especially in processes (for example, exocytotic secretion) that are brought about by an increase in the intracellular Ca^{2+} ion concentration.

We should also consider the possibility that conversion of phospholipids to other species which can rapidly cross a membrane bilayer (for example, fatty acids) may also affect membrane curvature in a similar fashion.

Whitepox virus isolated from hamsters inoculated with monkeypox virus

SINCE the eradication of smallpox in Equatorial Africa several 'new' pox viruses have been isolated in our laboratory from materials collected by WHO field workers—monkeypox virus from an affected individual and the 'whitepox' viruses from apparently healthy monkeys and rodents Monkeypox virus is not widespread but occasionally infects man and has caused death: 33 such cases have occurred in Africa, with 6 deaths. It is not known whether whitepox viruses are pathogenic for man but by laboratory markers they are indistinguishable from variola virus[1]. We report here that a whitepox virus identical to the whitepox virus found in feral monkeys and rodents in Equatorial Africa has now been isolated from the kidney and lungs of golden hamsters with an asymptomatic form of infection caused by intracordial inoculation with monkeypox virus. This result supports the hypothesis that natural whitepox viruses are white clones always present in populations of monkeypox virus.

Isolates from monkeypox virus population clones identical with whitepox viruses were shown to be stable and did not change their properties with serial passages on the chorioallantoic membrane of developing chick embryos[2]. As cloning is an artificial laboratory procedure we attempted to determine whether this change in monkeypox virus population occurs in a living host. We suspected the existence of such a mechanism on the basis of whitepox virus detection in African rodents (*Mastomys natalensis*) insusceptible to this virus.

Three-week-old golden hamsters (*Mesocricetus auratus*) inoculated intracordially with 0.5 ml of chorioallantoic monkeypox virus culture (Copenhagen strain) at a dose of 10^6 pock-forming units (PFU) were used as an experimental model. For virus isolation from visceral organs groups of inoculated animals were killed 3 days post infection and at 7-day intervals. At each stage the blood and organs of 10 to 40 animals were tested. Suspensions of 1 part tissue: 2 parts McIlvain buffer solution were prepared from the liver, kidney, lung, spleen, lymph nodes, brain and testis. Viruses were isolated on the chorioallantoic membrane (CAM) of 12-day-old chick embryos; incubation was for 72 h at 35°C. Pox antibodies in the serum were determined in haemagglutination inhibition (HAI) test (with 2 haemagglutination units of vaccinia virus), and in the neutralisation tests on chick embryos by pock reduction on the CAM using standard methods.

Hamsters inoculated with the virus intracordially as well as by intranasal and percutaneous routes showed no clinical symptoms of the infection. Pox antibodies were detected in nearly 50% of the infected hamsters. In animals in which antibodies were present they developed during the second week, reached the maximum by 4–5 weeks and disappeared 8–9 weeks post inoculation. Pox antibody titres were not high (the highest antihaemagglutinin titre did not exceed 80).

Within the first 3 days after inoculation virus was found in the blood and organs of almost all the animals examined. A week later virus was isolated from only 30% of the animals. The number of virus carriers continued to decrease: after 2 weeks 25% carried the virus, after 4 weeks 13%, and after 6 weeks, 9%. At 7 and 9 weeks post infection no virus was isolated from the hamsters. It should be emphasised that two and more weeks post inoculation the virus could be detected only in lungs and/or kidneys of the hamsters and was absent from blood.

Investigation of isolates obtained from the hamsters' organs 3 days, 1 week and later post inoculation showed that in a majority of cases they were identical with monkeypox virus used for inoculation. However, 4 of 35 isolates differed markedly from the parent virus: three had been isolated from kidneys 2, 3½, and 4 weeks post inoculation and one from lungs of the hamsters 4 weeks post inoculation. A more detailed study showed these viruses to be fully identical with natural whitepox viruses isolated from African animals as well as with variola virus. A comparison of two of these isolates with the parental strain of monkeypox virus and whitepox virus Chimp-9 is shown in Table 1.

Further passaging of 'white' isolates on the CAM of chick embryos did not change their properties.

Our results show that 'white' clones can be produced from a monkeypox virus population by a 'natural' mechanism as well as by cloning. In asymptomatic infections of hamsters induced by

Table 1 Comparison of 'white' isolates derived from kidneys of hamsters infected intracordially with monkeypox virus

		Isolates		Reference virus strains	
Markers		$\mathrm{MpW}_{\mathrm{Ham-1}}$	$\mathrm{MpW}_{\mathrm{Ham-2}}$	Whitepox (Chimp − 9)	Monkeypox (Copenhagen)
	Pock morphology†	White, dense	White, dense	White, dense	2 types flat with haemorrhages and single white
Chick embryos*	Lethality LD_{50} (PFU per 0.1 ml)	2.3	2.5	2.2	<1
	Accumulation in liver† (PFU per g tissue)	8.5	8.3	8.7	9.1
	Pock formation at 39°C	None	None	None	Yes
PEK marker		Positive	Positive	Positive	Negative
Neuropathogenicity for white mice§ LD_{50} (PFU per 0.03 ml)		6.3	4.6	4.4	2.7
Rabbit skin test at inoculation (dose, 10^6 PFU per 0.1 ml)	Intradermally	Scarce soft infiltrate	Scarce infiltrate	Scarce infiltrate	Dense infiltrate with necrosis
	On scarified skin	No reaction	No reaction	No reaction	Papulopustular eruption

Pock morphology was determined on CAM.

* Age of chick embryos at inoculation—12 days.

† Incubation post inoculation—72 h at 35°C.

‡ PEK marker—presence of CPE and haemadsorption of chick erythrocytes of the continuous pig embryo cell line infected with virus dose of 10^4 PFU.

§ Neuropathogenicity was determined on 10-day-old white mice at intracerebral inoculation.

monkeypox virus the population of monkeypox virus that persists in the organism undergoes certain changes. It seems likely that 'white' clones initially present at a low level (<5%) are preferentially selected for. This selection process occurs in an unpredictable manner and the factors controlling it are not known. It seems probable that the whitepox viruses detected in feral animals (including those not susceptible to them) are produced through a similar mechanism.

Finally, as whitepox viruses are indistinguishable from variola virus in all laboratory marker tests our results may be considered as a first experimental indication of a possible origin of variola virus from monkeypox virus.

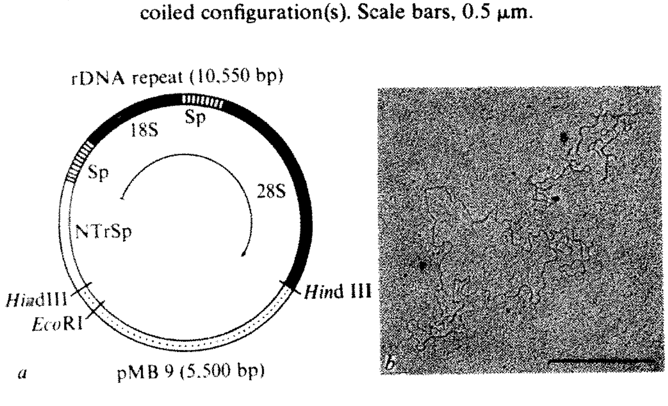
Transcription of cloned *Xenopus* ribosomal genes visualised after injection into oocyte nuclei

DNA CLONING and the direct visualisation of chromatin transcription by electron microscopy provide useful details of the structure and function of genes, but the value of these techniques would be even greater if they could be applied to the same genes or segments of DNA. Our previous work[1] on amplified ribosomal DNA (rDNA) of the water beetle *Dytiscus* showed that rDNA injected into oocytes is correctly transcribed. Gradients of growing rRNA fibrils could be unambiguously recognised as correct transcription when compared to the characteristic transcription pattern observed in the original cell type. We have now extended the usefulness of this technique to recombinant DNA, choosing as an example of a cloned vertebrate gene a single rDNA repeat of *Xenopus laevis* contained in plasmid DNA. The results show that this gene may be transcribed with remarkable fidelity in injected oocytes, and that untranscribed genes are converted into a characteristic chromatin structure.

Fig. 1 *a*, Diagram of pXlr 101. This is a single rDNA repeat of *Xenopus laevis* inserted into the plasmid pMB9 at the *Hin*dIII site. The rDNA repeat (10,550 base pairs) is orientated with the non-transcribed spacer (NTrSp, 2,350 base pairs) next to the *Eco*RI and *Hin*dIII sites of the plasmid. The rDNA coding region is limited at its 3′ end by a *Hin*dIII cut 50 base pairs before the end of the normal 28S transcription region. Normal rDNA transcription initiates and terminates where indicated by the arrow inside the diagram. DNA has been characterised as described in ref. 4. *b*, Electron micrograph of circular recombinant DNA used for injection. DNA was spread out for electron microscopy as described before[27]. The relaxed molecule (r) shown has a contour length of 5.06 μm (see Fig. 2*a*). Most molecules occur in a supercoiled configuration(s). Scale bars, 0.5 μm.



A pMB9-based recombinant plasmid (pXlr 101) was used; its composition[2–4] is summarised in Fig 1*a*. To determine the size distribution of DNA used for injection, purified DNA was spread for electron microscopy (Fig. 1*b*). More than 90% of the molecules were in supercoiled circular configuration. Relaxed circles revealed a homogeneous distribution of contour lengths (mean value 5.19 μm, Fig. 2*a*). To prepare nuclear spreads, oocytes from four *Xenopus* females were each injected with 50 nl DNA solution and a trace of ^{125}I–BSA, aiming for the nucleus[5]. Nuclei were isolated 8–18 h later, counted to identify successful nuclear injections, and spreads for electron microscopy prepared as before[1]. Injected molecules were clearly identified in nuclear spread preparations by the small size of the injected circles[1]. Almost all injected material was found as newly assembled chromatin[6,7], no large masses of 'naked' DNA being observed. Most of the beaded chromatin circles were seen as densely aggregated masses and could be individually identified only in the more dispersed peripheral parts of the preparations. Only clearly detached, open circular, molecules were measured and analysed further.

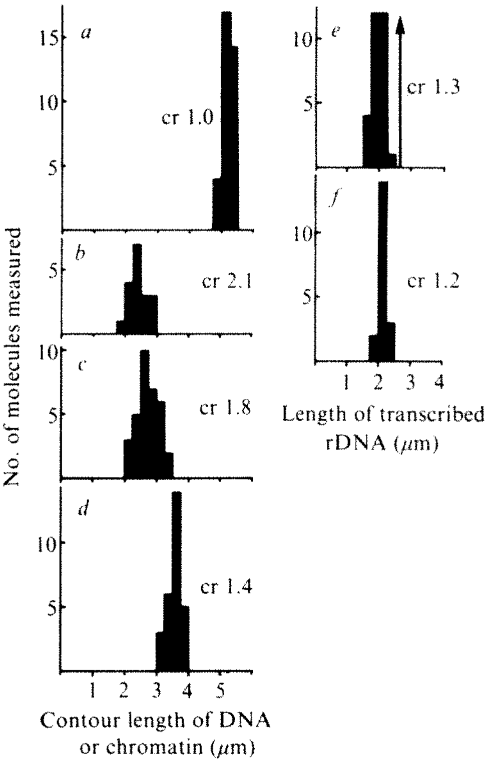


Fig. 2 Length distributions of DNA used for injection and of chromatin recovered from reisolated nuclei. *a*, DNA spread with cytochrome *c*. *b*, Beaded chromatin circles without apparent transcriptional complexes. *c*, Chromatin circles with sparse irregular transcriptional activity. *d*, Chromatin circles with fully transcribed regions, presumably the rDNA insert. The numbers designated cr in each histogram indicate the compaction ratio of DNA in the chromatin circles compared to the length of fully extended pure DNA (*a*). *e* And *f* show the lengths of the fully transcribed chromatin regions which carry transcripts. *e*, Chromatin circles from injected nuclei. *f*, Endogenous amplified rDNA. The arrow in (*e*) indicates the fully extended length of rDNA which can carry transcribed sequences. All measurements shown in *b*–*f* were made on the same single nuclear spread preparation.

Our reasons for claiming that cloned rDNA can be treated normally in injected oocytes depend on its structure as tran-

0028-0836/78/0276—0292$01.00

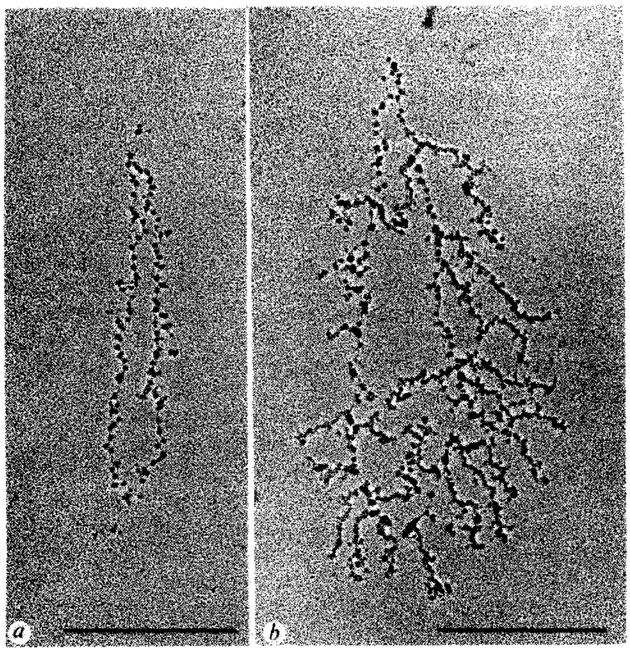

Fig. 3. Spread preparations of injected oocyte nuclei, showing circular chromatin. Oocyte nuclei were injected with purified DNA, incubated for 8 or 18 h (see text); individual nuclear contents were dispersed in low salt medium, and processed for electron microscopy with positive staining and rotary shadowing as before[1]. *a*, A regularly beaded chromatin circle with no apparent transcriptional activity (contour length 2.43 μm). *b*, A typical example of the sparsely transcribed circle (contour length 3.10 μm). Note the irregular spacing of polymerases and the varying length of the lateral fibrils. These circles are taken from the same nuclear preparation as was used for histograms *b* and *c* of Fig. 2.

scribed or untranscribed chromatin. Injected DNA circles can be classified as non-transcribed or transcribed depending on whether lateral RNP fibrils are absent or present respectively.

The great majority of chromatin circles have a regularly beaded ultrastructure (Fig. 3*a*; 80–90 beads per circle; diameter of the particles after positive staining and rotary shadowing, 12–20 nm) and a mean contour length of 2.45 μm (Fig. 2*b*). This suggests that the injected DNA is assembled into a regular nucleosome structure since it appears to have 180–200 base pairs DNA per nucleosome repeat (see ref. 8). There is a 2.1-fold compaction of the original DNA into chromatin as visualised after dispersion in low-salt medium. A similar compaction was obtained after injection of various other samples of circular DNA, including pMB9 DNA and a recombinant pMB9 plasmid containing four *Xenopus laevis* 5S DNA repeats (data not shown). These results are in agreement with calculations made for spread linear chromatin from various eukaryotic cell types[9–11].

The identification of transcriptionally active chromatin is based on the presence of nascent ribonucleoprotein (RNP) fibrils (see ref. 12 for limits of detection and refs 13, 14 for distinction between nucleosomes and RNA polymerases in nuclear spread preparations). Transcriptional complexes on injected circles were observed in 6 out of 21 preparations of spread nuclear contents. On each of these six grids more than 90% of the injected material was assembled into transcriptionally inactive chromatin. Transcriptionally active chromatin was classified as sparsely or densely transcribed according to the packing and arrangement of polymerases and the lengths of the attached RNP fibrils. We have seen about equal numbers of sparsely or densely transcribed chromatin circles. Sparsely transcribed chromatin (see Fig. 3*b* for a typical example) has a regularly beaded structure interspersed with a low number of irregularly spaced polymerases (3–10 polymerases per μm chromatin). The attached RNP fibrils show no graded length distribution and are up to 0.80 μm long. In some cases such circles contain short segments (0.2–1.2 μm) with closely packed polymerases (30–50 polymerases per μm) carrying transcripts of irregular length. The average contour length of these sparsely transcribed circles is 2.77 μm (Fig. 2*c*); this is greater than the mean length of the non-transcribed molecules.

Densely transcribed chromatin has at least 1.6 μm of closely packed polymerases bearing transcripts of gradually increasing length. We interpret the molecules shown in Fig. 4*a*, *b* as examples of correct transcription of cloned *Xenopus* rDNA. Molecules of this kind, of which we have measured 28 examples, show a detailed morphological similarity to the transcription units of endogenous amplified rDNA from the same nucleus (Fig. 4*c*). Circles of the kind shown in Fig. 4*a*, *b* are characterised by having three regions: (1) A densely transcribed region, which includes the 18S, 28S sequences. (2) A non-

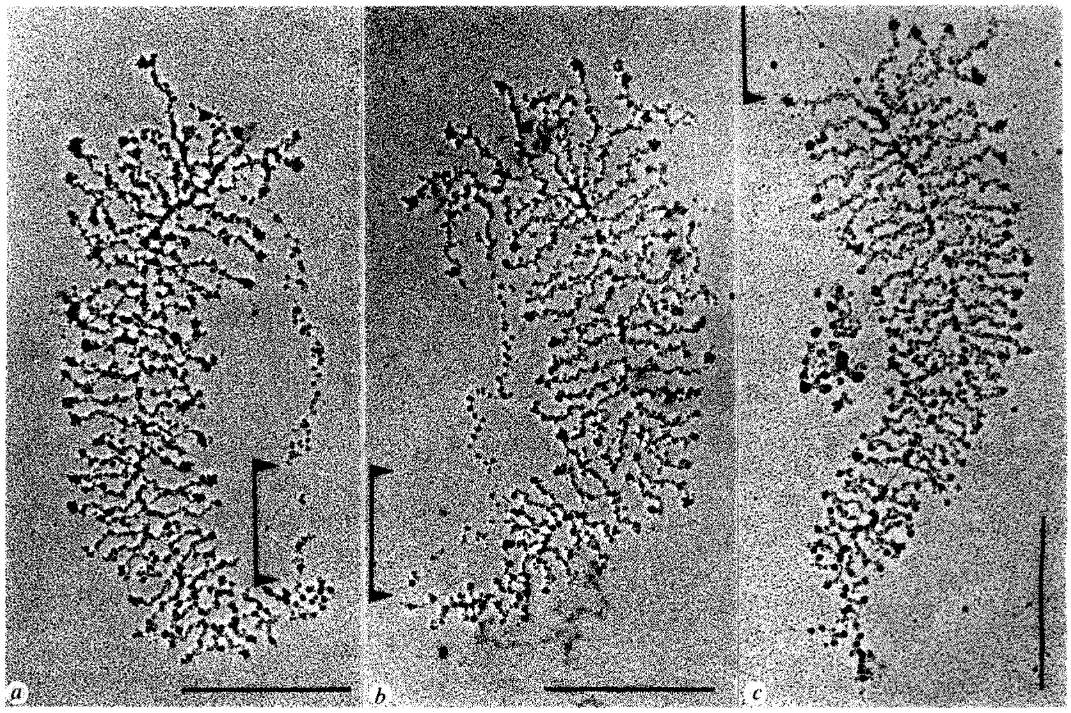

Fig. 4 Ribosomal DNA transcription patterns of injected recombinant plasmid circles (*a*, *b*) and an endogenous rDNA segment (*c*) seen in the same preparation. The morphology of the transcription units is identical by the criteria of density and size of rDNA-attached polymerases, the lengths and gradient arrangement of lateral fibrils, and their terminal coiling which results in dense, knob-like structures. Note the predominantly unbeaded structure of the 'spacer' segments in both figures (arrows).

transcribed stretch of DNA with a 'smooth' ultrastructure: this precedes the densely transcribed 18+28S region, and probably corresponds to the 'non-transcribed' spacer sequences (3) A regularly beaded region without detectable transcriptional activity, presumably representing the pMB9 plasmid DNA. Within the transcribed regions, polymerases are densely packed (30–50 polymerases per μm), and lateral precursor rRNP fibrils are arranged in a typical length gradient, with terminal fibrils up to 0.40 μm in length frequently ending in knob-like structures. The length of chromatin which bears transcripts is 1.63–2.34 μm (mean 1.98 μm; see Fig. 2*e*); this is conspicuously similar to the length of transcribed regions of endogenous amplified rDNA seen on the same preparations (range 1.90–2.39 μm, mean 2.14 μm; see Fig. 2*f*) and reported in other studies[2,15–19]. The 'spacer' segments of injected rDNA are seen as predominantly 'smooth' stretches (mean length 0.63 μm); they are located before the start region (5′ end) of the transcribed regions, and are characterised by a greatly reduced number or complete absence of associated granular particles, in contrast to the beaded structure of the plasmid chromatin adjacent to the 3′ end of the rDNA insertion.

Figure 2*d* shows that the circles containing densely transcribed rDNA (mean contour length 3.61 μm) are compacted 1.4 times compared to the length of the fully extended DNA before injection (Fig. 2*a*). This is considerably less compaction than is seen in non-transcribed or sparsely transcribed rings obtained from the same preparation (Fig. 2*b*, *c*). Circles with a densely transcribed rDNA insert allow a precise comparison of the structural configuration of DNA in transcriptionally active and inactive regions. The 8,200 base pairs of transcribed rDNA is 2.64 μm as pure DNA and 1.98 μm as transcribed chromatin; this represents compaction of 1.3, and shows that transcribed rDNA is almost fully extended (Fig. 2*e*, *f*). A similarly extended DNA configuration can be calculated for most of the smooth 'spacer' regions (see also refs 13, 14, 18, 20).

The precision with which injected rDNA may be transcribed is remarkable The existence of a gradient of transcript lengths suggests that all initiations have taken place at the same point. The typical length of chromatin densely packed with polymerases indicates that transcription is terminating at the correct distance after initiation, as is also implied by the typical length of the longest transcripts. The nucleosome-free region of chromatin immediately in front of the initiation site is characteristic of rDNA transcription. We conclude that a single ribosomal gene repeat contains sufficient information in its DNA sequence to promote accurate transcription, and that this can take place on a relatively short length of DNA, as previously demonstrated biochemically for 5S genes[21] and 4S genes[22,23]. The transcription of the injected rDNA is resistant to low levels of α-amanitin, indicating that it is not transcribed by polymerase II; the accurate morphology of the densely transcribed rDNA suggests that it involves the use of polymerase I.

One of the most interesting general conclusions to emerge from the electron microscopy of nuclear spreads is that the transcription of ribosomal genes is not regulated simply by the supply of RNA polymerase, but seems to be governed by some component which makes a gene either wholly unavailable (closed) or maximally available (open) for polymerase attachment and transcription. Evidence for the existence of such a component has been implicated in previous nuclear spread studies. In amphibian oogenesis[24], as also in *Drosophila* spermatogenesis[25] and blastoderm embryos[26], most ribosomal genes are not transcribed, but a minority are maximally packed with actively transcribing polymerases. If ribosomal gene transcription were regulated by the availability of RNA polymerase molecules, most genes should have had a small number of widely spaced polymerases. The existence of a component which makes a gene open or closed for polymerase attachment is indicated very clearly in our own experiments reported here. By injecting about 10^9 genes into an oocyte, we are increasing by two to three orders of magnitude the endogenous ribosomal gene content of an oocyte nucleus (2×10^6 genes) and by 10^6 the normal content of a somatic nucleus (10^3 genes). Therefore we certainly have an experimental condition in which genes greatly exceed the abundance of their polymerase. We would never expect to see the dense packing of polymerases on a gene (as shown in Fig. 4) in the absence of the postulated gene control component. The fact that we have used cloned genes ensures that all the injected DNA circles which we observe are equally capable of being transcribed. There is otherwise the possibility that some of the untranscribed endogenous genes may be genetically altered and incapable of transcription. Finally, the fact that we inject genes as purified DNA demonstrates particularly clearly that oocytes have available a limited supply of the ribosomal gene-controlling component. This experimental system can now be used to determine whether a similar component affects the transcription of non-ribosomal genes.

Thus, our results indicate that a single ribosomal gene cloned in bacteria can be correctly transcribed after the injection of recombinant plasmid DNA into oocyte nuclei. This encourages the use of injected oocytes to investigate the structure and function of unknown segments of chromosomal DNA which have been cloned in bacteria.

We thank R. H. Reeder (Carnegie Institution, Baltimore) for the initial supply, and D. A. Melton for the growth, of the rDNA plasmid used; also Miss S. Whytock for assistance. Dr W. W. Franke of the German Cancer Research Centre, Heidelberg, and R. A. Laskey, D. A. Melton, and E. De Robertis for helpful advice. Sequences from the genome of a non-transforming mutant of polyoma virus

POLYOMA, the small DNA animal tumour virus, like the SV40 virus, has attracted interest because its genome is small enough to be analysed at the molecular level[1–6], enabling study of the molecular basis of oncogenic transformation. In polyoma virus there are several deletion mutants, designated *hr-t* (host-range transformation) mutants, which are unable to transform cells (or cause tumours) and which will grow in certain types of cells only, mainly those which have already been transformed. We report here that we have sequenced the region of the DNA which probably determines the non-transforming phenotype of one such *hr-t* mutant (NG-18)[7] and compared it with the sequence of wild-type polyoma virus DNA. These studies show NG-18 to be a frame-shift mutant, and to have lost 187 of the nucleotides present in wild-type DNA, including several nucleotide triplets which code for cysteine.

NG-18, as well as other *hr-t* mutants, contains a deletion in the 'early region' of the polyoma virus genome[8,9]. This region is thought to contain the coding information for at least three antigenically related proteins, which have been called 'small T-antigen', 'large T-antigen' and membrane-associated or 'middle T-antigen'. The early region probably contains the information required for transformation. The general properties of *hr-t* mutants are as follows: their genetic defect can be rescued[8] by the polyoma virus wild-type restriction fragment *Hpa*II-4, which maps between 78.4 and 91.6 units on the DNA physical map (see Fig. 1); the deletion in NG-18 has been more precisely defined to lie within a *Hae*III subfragment of *Hpa*III-4[8]. A protein the size of small T-antigen (molecular weight 21,000–22,000) is absent from cells infected with *hr-t* mutants[9,10], but a protein indistinguishable in size from the large T-antigen (MW ~ 100,000) is produced[10,11]. *Hr-t* mutants and *ts* *A*-gene mutants (the *A* gene is thought to code for large T-antigen[11]) complement each other for both transformation and virus production[12,13]. Cells infected with *hr-t* mutants also seem to lack a protein (MW ~ 55,000) which occurs in wild-type lytically infected and transformed cells[9,10], is associated with membranes[16] and seems to contain some tryptic peptides in common with small T-antigen[14].

To look in more detail at *hr-t* mutants, we have determined the DNA sequences of the *Hpa*II-4 restriction endonuclease fragment of wild-type polyoma virus DNA (A2 strain)[15] and have compared this with the corresponding DNA sequence found in the *hr-t* mutant, NG-18.

Before sequencing, a fine-structure restriction endonuclease map of *Hpa*II-4 was determined (Fig. 1*b*). Previous analysis of NG-18 DNA with restriction endonucleases showed it to have a deletion of about 3% which mapped at 80–85 units on the physical map of wild-type polyoma virus DNA[4], and to lack the *Sst*I and one of the *Ava*I restriction endonuclease sites found in *Hpa*II-4 (M. Fried, unpublished results). Our studies showed that the fifth largest *Hinf*I restriction endonuclease fragment in polyoma virus DNA contained the NG-18 deletion (Fig. 1*c*) and we used this fragment for sequence analysis across the deletion of the mutant DNA (Fig. 2).

A comparison of sequences found in wild-type polyoma virus DNA (A2 strain) and NG-18 DNA (Fig. 2) gave the following results. (1) Except for the deleted region, the sequences found between 78.4 and 91.6 map units (*Hpa*II-4) in polyoma virus A2 DNA were indistinguishable from those found in the corresponding region of the DNA in NG-18. (2) In NG-18 DNA, 187 base pairs (relative to A2 DNA) were missing, and the deletion could be mapped to lie between 80.5 and 84 units on the physical map. (3) There are many sequences in the region between 79 and 86 map units (Fig. 3) which contain translational termination codons, but these are present in two reading frames only. The third frame contains no termination codons and is presumably used for translation. Following the deletion in NG-18, the sequence does not re-enter the reading frame which has no termination codons, but rather re-enters another reading

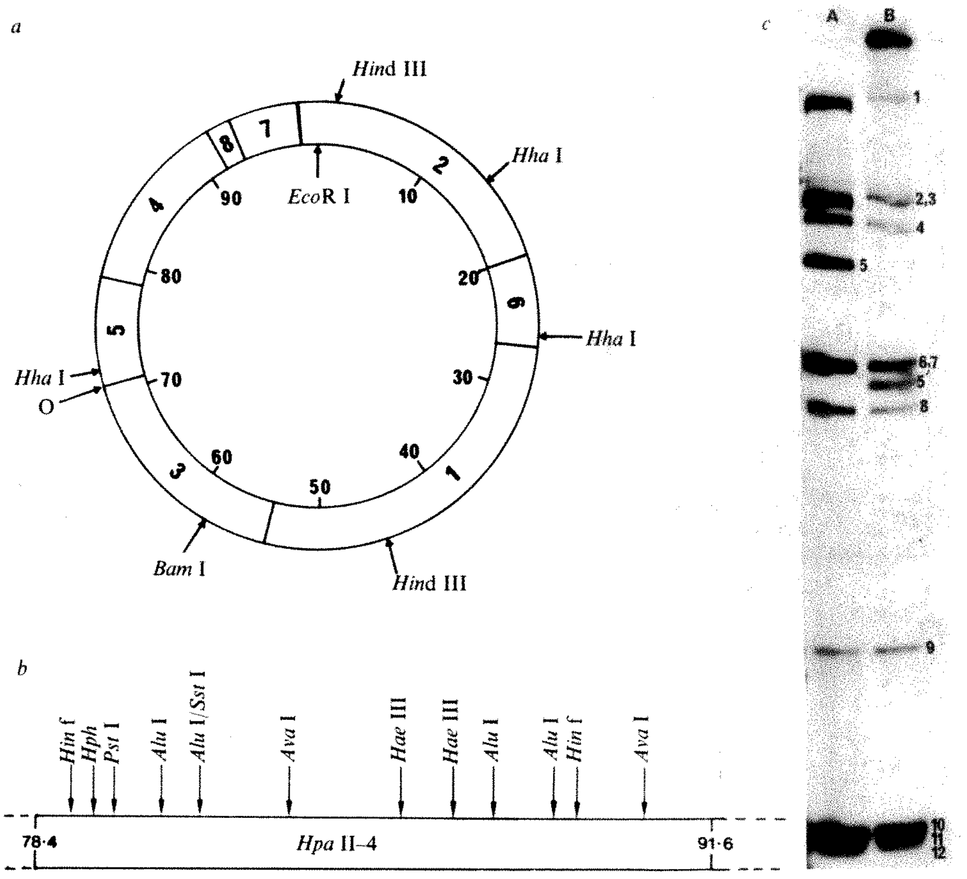

Fig. 1 *a*, The *Hpa*II restriction endonuclease map (100 units) of polyoma virus DNA (A2 strain) showing the region containing the origin of viral replication (O) (taken from ref. 15). *b*, An expanded restriction endonuclease map of the *Hpa*II-4 fragment. *Hpa*II-4 contains the functional deletion found in the *hr-t* mutant, NG-18. The restriction endonuclease sites shown have been independently mapped (ref. 23, Fried, unpublished, and B. E. G., unpublished) and have also been confirmed by sequence analysis (ref. 3 also, see Fig. 3). *c*, An autoradiogram showing A2 (A) and NG-18 (B) DNAs which have been cleaved with the restriction endonuclease *Hinf*I and separated by electrophoresis on a 5% acrylamide–bisacrylamide gel (20× 40 cm)[15]. *Hinf*I cleaves polyoma DNA into 12 fragments, the fifth largest of which is found in *Hpa*II-4 (B. E. G., unpublished). This fragment, which is about 10.5% the size of A2 DNA, occurs as a fragment about 7% in size in NG-18. The NG-18 *Hinf*-7% fragment (band 5' in channel B) has been used to determine the sequences 'missing' in the mutant DNA (see Fig. 2). Cleavage of the ^{32}P-terminally labelled A2 *Hinf*-10.5% fragment with *Hae*III gave new fragments about 7.0 and 2.5% in size; cleavage of NG-18 ^{32}P-terminally labelled *Hinf*-7% gave fragments about 3.5 and 2.5% in size. Sequences from the larger fragment in each case are shown in Fig. 2.

frame, and a termination signal is met within two codons of the deletion. (4) In the 'open' reading frame between 79 and 86 map units, the codon TGT occurs six times and TGC four times in wild-type polyoma DNA. These are cysteine codons. In NG-18 DNA, all but two of these codons are absent.

The data which concern the deletion of NG-18 are summarised in Fig. 3. What conclusions do these data allow? First, as the genetic defect in NG-18 was found to be rescued by the restriction fragment *Hpa*II-4 (ref. 8), and as, except for the deletion found in NG-18, our sequence analysis has shown the mutant and wild-type DNAs to be indistinguishable over this region, it can reasonably be assumed that the deletion is responsible for the mutant phenotype. Second, as NG-18 is essentially a frame-shift mutant, and as the sequences which immediately follow the deletion include a termination codon, any protein(s) induced by the mutant would be smaller than might be expected from a consideration of the size of the deletion alone. Third, the translation product expected from the wild-type DNA would contain a large number of cysteines, whereas a protein from the corresponding region of NG-18 would lack most of these cysteines. If this region of the genome of wild-type virus is coding for a functional protein, the removal of a large number of cysteines would almost certainly alter the conformation of the protein and would be expected to alter its function.

As the large T-antigen proteins made by NG-18 and polyoma wild-type DNA are indistinguishable in size[10,11], it is highly probable that the region of the DNA covered by the deletion is

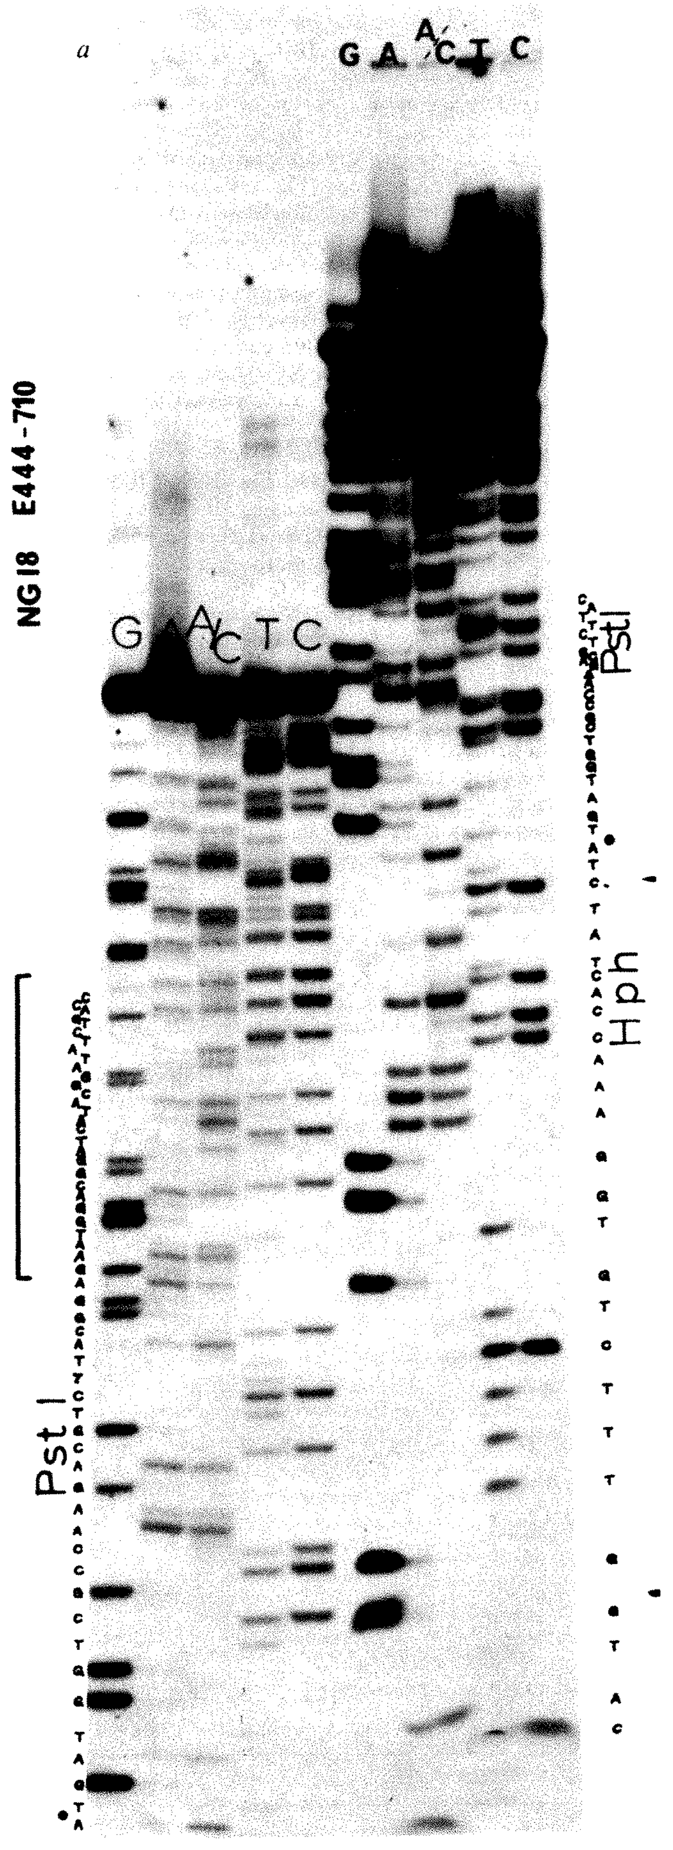

Fig. 2 Polyoma virus DNA and DNA from the *hr-t* mutant NG-18 were cleaved with the restriction endonuclease *Hinf*I. Fragments were labelled at their 3' ends using [α-^{32}P]dATP and the other three cold deoxynucleotide triphosphates (TTP, dCTP and dGTP) in the presence of T4 polymerase[21]. The A2 *Hinf*-10.5% fragment and NG-18-7% fragment (Fig. 1*c*) were isolated, further cleaved with *Hae*III[23], and the sequences of the appropriate fragments (now labelled at one end only) were determined using the techniques described by Maxam and Gilbert[22]. *a*–*c* show autoradiograms of 20% acrylamide–bisacrylamide ges (20 × 40 cm) made essentially as described by Sanger and Coulson[24]; samples were loaded on to the gels at two different time points. The sequence of more than 100 nucleotides can be read from these gels. *a*, The early strand (E) sequence (which contains information complementary to that found in the early mRNAs[25]) from near the *Hinf*I site (79 map units) in NG-18 DNA to a position which corresponds to about 84.3 units on the physical map of polyoma virus DNA (A2 strain) (Fig. 1). (The sequence is underlined by a solid line in Fig. 3.) *b*, An enlargement of the part of *a* which indicates where the deletion occurs in NG-18 (between CAT and ACG in left half of the figure). *c*, The early strand sequences (E) from near the *Hinf*I site in wild-type polyoma virus DNA (A2 strain) to a position five nucleotides beyond the *Sst*I site (GAGCTC) at about 8.6 map units. This sequence is underlined by a dashed line in Fig. 3.

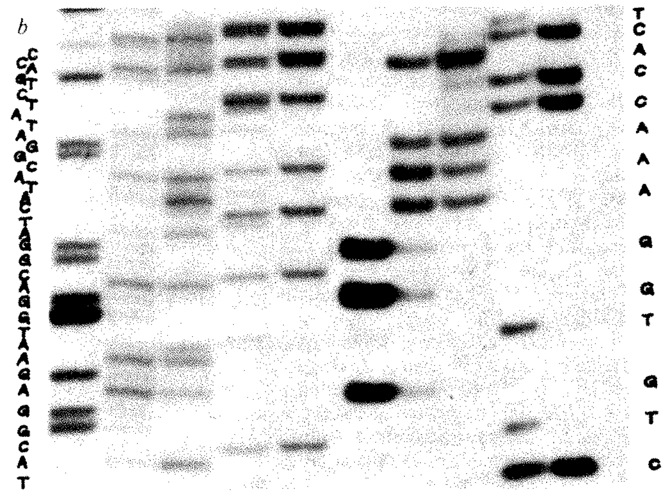

not a coding region for large T-antigen. This implies that in polyoma virus, large T-antigen is either coded for by sequences which occur after 84 map units on the physical map of the DNA (that is, clockwise from 84 map units, see Fig. 1) or large T-antigen is made from a 'spliced' mRNA, such as have been reported for SV40 and adenoviruses[19,20]. The latter argument is supported by several facts: assuming large T-antigen to be entirely virally coded[4], there is not enough coding information left in the 'early region' beyond 84 map units to make a protein the size of large T-antigen. Moreover, among the early mRNAs of polyoma virus, there is an mRNA species that has a splice between 80 and 86 map units; this is postulated to be the mRNA for large T-antigen (R. Kamen, personal communication).

The polypeptide expected from translation of the sequences of polyoma virus DNA found between 79 and 86 map units is shown in Fig. 3*b*. These sequences show some homology (underlined) to sequences predicted to exist in the small T-antigen of SV40 (ref. 18). Although the homology is not extensive, the fact that it exists, that polyoma virus and SV40 seem to share a common overall organisation[4], and that the NG-18 mutant (as well as other *hr-t* mutants) fails to induce small T-antigen, all suggest that sequences which lie between 80.5 and 84 units on the physical map of polyoma virus DNA code for a part of small T-antigen. It seems reasonable to assume, therefore, that small T-antigen may have a rôle in transformation.

c

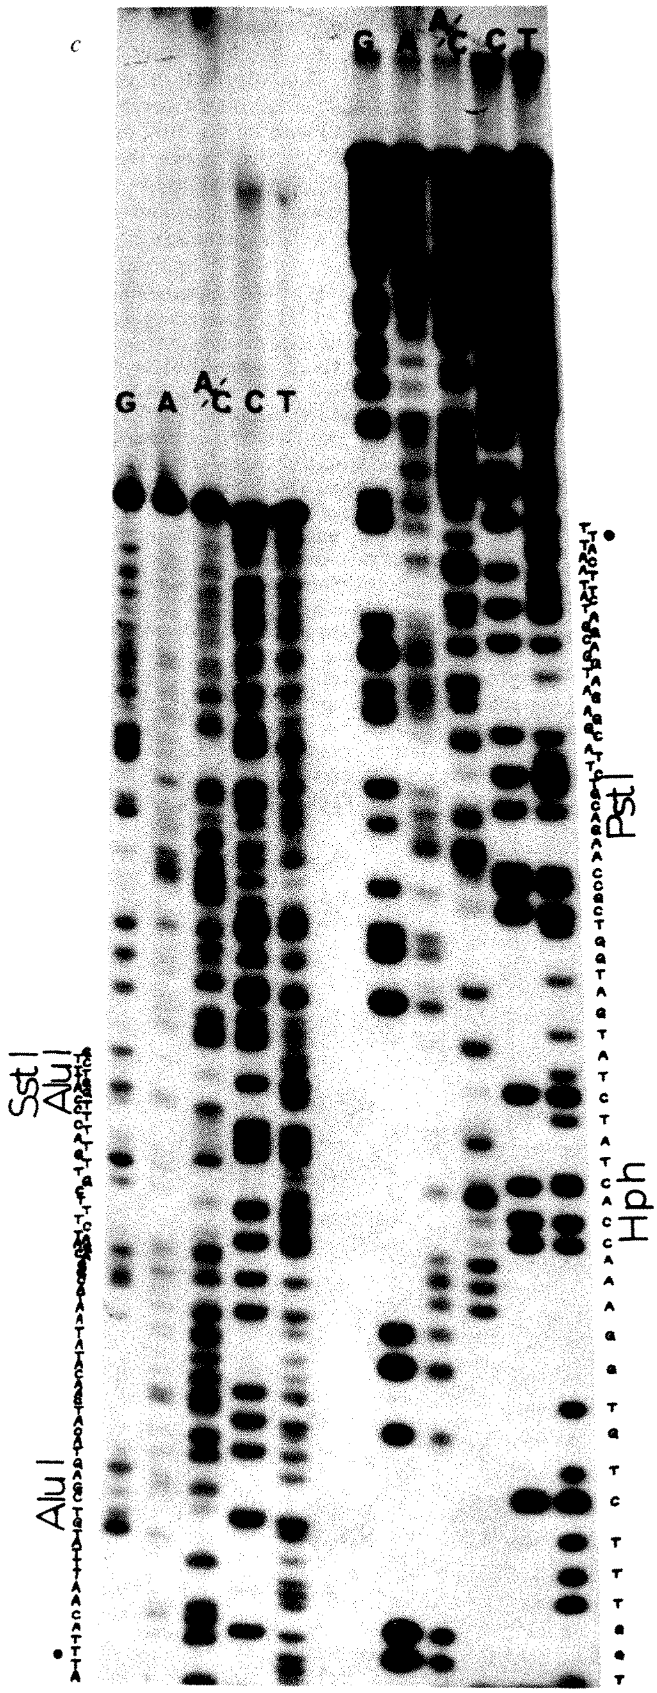

Fig. 3 *a*, Some of the sequencies found in the DNAs of wild-type polyoma virus (A2 strain and the *hr-t* mutant NG-18. DNA sequences designated 'late strand' correspond to sequences found in the early mRNAs[25]. Sequence data for A2 DNA from about 79–86 map units are taken from gels shown in Fig. 2 or from data presented elsewhere[3]. (Numbers shown here and on gels in Fig. 2 represent the number of nucleotides from the *Hpa*II 3–5 junction in polyoma DNA which has been designated the 'zero-point' of the sequence.) NG-18 DNA sequence data are taken in part from the gel shown in Fig. 2. As the parent strain of NG-18 is not known, sequences from other parts of *Hpa*II-4 of mutant DNA were determined, data not given. No differences were seen between mutant and wild-type DNAs. Sequences found in A2 DNA but not in NG-18 DNA are shown within the brackets. Termination codons (TGA, TAG, TAA) are underlined. It can be seen that within this region of the wild-type DNA, only one frame can be used in translation if TGA, TAG and TAA are read as termination codons. The first termination codon found within the 'open' reading frame lies at about 86 map units and is indicated by a box. The protein(s) made from this region of the DNA can be seen to be remarkably cysteine rich (CYS). A protein induced by the NG-18 mutant should lack 8 of the 10 cysteine residues that can be predicted to be found in a protein induced by A2 DNA. *b*, The amino acid composition of a polypeptide predicted by the sequences shown in *a*. Amino acids shown inside the brackets would be absent in a protein translated from NG-18 DNA. Homologous regions between the predicted polypeptide of polyoma virus and small T-antigen of SV40 are underlined[18]; dashed lines show where very similar (ARG/LYS or LEU/ILE) sequences are observed

The data obtained from sequencing NG-18 DNA do not allow this role to be assigned exclusively to either the cysteine-rich part of the protein or its normal C terminus, as both should be lacking in a protein induced by NG-18.

For SV40, several viable mutants have been isolated[26] in which deletions occur in a part of the SV40 genome which is comparable to the region in polyoma virus genome where the *hr-t* mutants have been mapped. These mutants fail to induce a protein the size of small T-antigen of SV40 (ref. 27) but do induce 'new' smaller proteins. Although the deletions in the SV40 mutants seem to have an effect on transformation, unlike the deletions in polyoma virus *hr-t* mutants, they do not entirely inhibit it[28,29]. Further studies on other polyoma *hr-t* mutants and the SV40 mutants may therefore provide some insight into transformation.

One further point remains to be considered. No protein comparable to the membrane-associated (MW ~ 55,000) protein reported for polyoma virus[16] has been found for SV40. As NG-18 also fails to induce this protein, it may also be coded for by sequences which lie between 80.5 and 84 map units on the physical map of polyoma virus DNA, and may also play a part in transformation. One of the next problems for study will be to determine whether the phenotypic differences between the polyoma virus and SV40 mutants are associated with small T-antigen or the membrane-associated protein, or possibly with both.

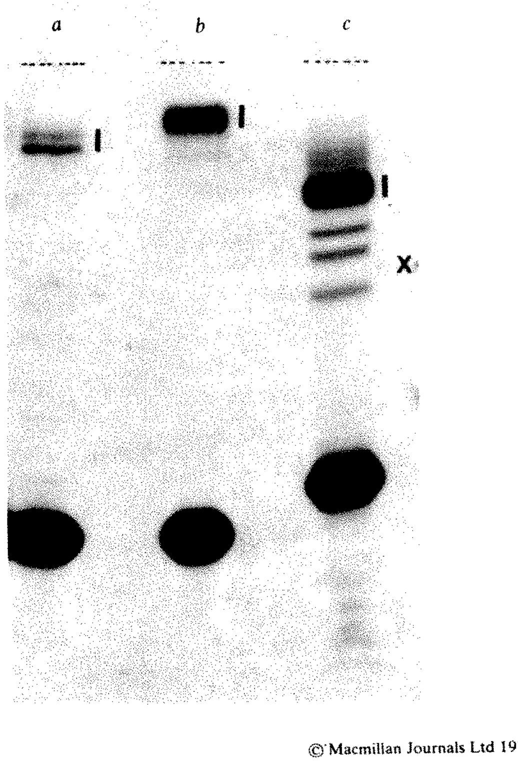
3′-Terminal nucleotide sequences in the genome RNA of picornaviruses

IN common with eukaryotic cellular mRNAs[1–3], the terminal sequences in virus RNAs contain untranslated regions of variable length[4–11]. These regions are likely to contain binding sites for macromolecules involved in functions such as replication[4] and translation[4–6] of the RNA, and assembly of virus particles. We report here that, as a first step in identifying these sites we have sequenced between 33 and 156 nucleotides next to the 3′-terminal poly(A)[12–14] of representative viruses from three of the four picornavirus genera[15], the enteroviruses, cardioviruses and foot-and-mouth disease viruses (FMDV). The viruses chosen for these analyses allow us to make comparisons of the 3′-terminal sequences both within and between the three genera. Within each genus the 3′-terminal sequences are at least 60% homologous, whereas viruses from different genera show little similarity. The 3′-terminal sequences also show some unexpected features, including the lack of the putative signal sequence 5′-AAUAAA-3′ (ref. 1) in viruses from two genera.

The virus RNA was partially[16] copied into complementary DNA (cDNA) from the poly(A) with an oligo(dT)-containing primer and DNA polymerase I as described previously[17], except that the cDNA was further purified (Fig. 1) so as to select only the larger DNA copies. These copies, not less than 43 nucleotides in length (primer included), were sequenced using the rapid

Fig. 1 Gel electrophoresis of [5′-^{32}P] complementary DNA synthesised with the RNA of *a*, SVDV; *b*, poliovirus; *c*, FMDV, type SAT 2. The cDNA was synthesised in an incubation[17] (1 h at 37 °C) containing: virus RNA (2–20 μg) purified as described elsewhere[32], Tris-HCl *p*H 7.5 (67 mM), $MnCl_2$ (0.5 mM), β-mercaptoethanol (0.13 mM), NaCl (0.16 mM), [5′-^{32}P] $p(dT)_{10}dG$ or [5′-^{32}P] $p(dT)_8dC$ (~100 pmol) purified as described previously[17], all four unlabelled deoxytriphosphates (each 0.67 mM), actinomycin D (50 μg ml^{-1}) and DNA polymerase I, Klenow fragment (4–8 units). Subsequently, the cDNA was isolated by phenol/chloroform extraction and ethanol precipitation. The transcription products were then separated by electrophoresis for 2–3 h at 900 V in a 15% polyacrylamide (0.6% bisacrylamide) gel (20 × 40 cm) containing 50 mM Tris-borate, 1 mM EDTA and 7 M urea, as shown. The bands migrating more slowly than the xylene–cyanol FF marker (×), indicated by a bar, were visualised by autoradiography and the cDNA eluted into water by homogenisation (4 extractions), then precipitated in a volume of 3.0 ml containing 0.05 M NaAc *p*H 5.4, 60 μg carrier RNA and 75% ethanol. The intense, fast migrating bands at the bottom of the diagram contain unincorporated primer, [5′-^{32}P] $p(dT_8)dC$ in lanes *a* and *b*, and [5′-^{32}P] $p(dT)_{10}dG$ in lane *c*.



0028–0836/78/0276—0298$01.00

chemical sequencing technique for [5′-^{32}P]DNA (ref. 18). Figure 2 shows polyacrylamide gels displaying sequences complementary to the 3′-terminal regions of several picornavirus RNAs. The clarity of the band patterns indicates that transcription occurred exclusively from the poly(A), and allows 3′-terminal sequences to be read without difficulty. The 3′-terminal sequence of encephalomyocarditis virus (EMCV) RNA has previously[17] been determined up to position 129 by the chemical method, and also in part by independent DNA and RNA sequencing techniques which indicated that the chemical method is reliable. In the present study, the chemically determined 3′-terminal sequences of poliovirus RNA (type 1, Mahoney strain) and FMDV RNA (type A, strain 61) have also been checked by other methods (not shown). In the case of poliovirus RNA, the sequence between positions 10 and 39 has been verified by the dideoxynucleotide method[19], with reverse transcriptase as the copying enzyme and a dideoxynucleotide to deoxynucleotide ratio of 2.5:1. The 3′-terminal sequence of 20 nucleotides in the FMDV RNA was verified using the 'plus–minus' method[20,21].

The few nucleotide sequence uncertainties were, as expected, near the 3′-end of the cDNA (Fig. 3), where gel resolution was not perfect. One anomaly was observed in poliovirus cDNA (not shown) in that at nucleotide 92, a dG and a dC apparently occur in the same position. This may be due either to anomalous gel mobility caused by strong secondary structure[19] or to heterogeneity in nucleotide sequence in one position[22].

The 3′-terminal sequences for nine picornaviruses, determined in at least two independent experiments, are shown in Fig. 3. In all polyadenylated RNAs previously examined[1,3,23,24] (except possibly Rous sarcoma virus RNA[25]), the sequence 5′-AAUAAA-3′ is located in a similar position in the untranslated region near the poly(A). This sequence has been implicated as a signal in polyadenylation[17] as it is absent from plant virus RNAs, which are not polyadenylated[8]. The same A-rich hexanucleotide is also present in EMCV (ref. 10) and maus-Elberfeld virus (MEV) RNAs near the poly(A), but is absent from the 3′-terminal region in the two enterovirus and five FMDV RNAs examined here (Fig. 3). (Although GAUAAA is present in swine vesicular disease virus around position 40, its presence must be considered fortuitous, as it is located much further from where AAUAAA is normally found[1–3], and is absent from the corresponding region of poliovirus RNA.) The absence of an AAUAAA sequence near the 3′-end in the RNAs of the enteroviruses and FMDVs, all of which are polyadenylated, therefore brings into doubt the suggestion[17] that this A-rich sequence is a universal signal for polyadenylation.

In the cardioviruses, a cluster of seven nonsense triplets occurs near the poly(A), with a frequency much greater than would be expected in a random sequence. At least two nonsense triplets block all three protein synthesis reading frames[10], suggesting this as a possible device for preventing protein synthesis continuing into the poly(A) as a result of a frameshift mutation, or suppression of the natural termination codon of the coding region. Nonsense triplets are almost as numerous in the enteroviruses, though more widely spaced. As with the cardioviruses, they occur in the three possible reading frames, but with only two of the frames blocked more than once. Inspection of the positions of the nonsense triplets in all the picornavirus RNAs allows the minimum number of untranslated nucleotides next to the poly(A) to be deduced. The highest number so far (43) is in serotype SAT 2 of FMDV.

Unexpectedly, we found that two classes of cDNA are synthesised with the RNA of the C997 strain of FMDV (Fig. 2). The larger cDNA (C997(L)) is ~60–70 nucleotides long and is very similar in sequence to the p(dT)$_{10}$dG-primed cDNAs from four other FMDV RNAs (Fig. 3). The smaller cDNA (C997(S)) is ~43–53 nucleotides long and is identical in sequence to C997(L) in the 20 nucleotides next to the oligo(dT) primer; then, in complete contrast to C997(L), there is a run of at least 13 dA residues, giving a total of 17 consecutive dA residues (Fig. 2). Therefore, there seems to be an oligo(U) tract in some C997 virus RNA molecules near the poly(A). An alternative explanation is that the oligo(dA) is an artefact resulting from slippage of the DNA polymerase on reaching a short run of U residues in the template, but this is considered unlikely, for once DNA synthesis has been initiated, slippage is not known to occur with DNA polymerase. It is also unlikely that slippage would occur on only some template molecules. Preliminary RNase T$_1$ two-dimensional fingerprinting experiments with C997 virus RNA have shown the presence of a spot, the position of which would agree with both the size and composition of the oligo(U) tract detected in the sequencing studies (D.N.B. and K. J. H. Robson, unpublished data).

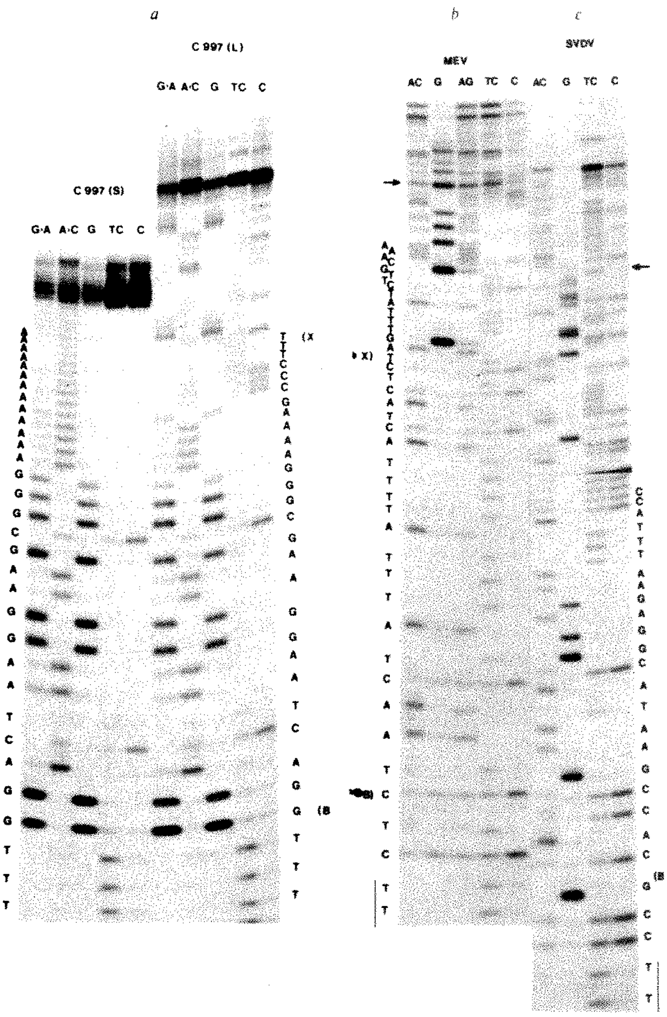


Fig. 2 Sequencing gels of *a*, [5′-^{32}P] p(dT)$_{10}$dG-primed cDNA synthesised with FMDV RNA, strain C997; *b*, [5′-^{32}P] p(dT)$_8$dC-primed cDNA from maus-Elberfeld virus RNA; *c*, [5′-^{32}P] p(T)$_8$dC-primed cDNA from SVDV RNA. The [5′-^{32}P] cDNA eluted from the polyacrylamide gel (Fig. 1) was divided into four or five equal volumes and each aliquot subjected to one of the six base-specific partial chemical degradations[18] (dG > dA, dA + dG, dA > dC, dG, dT + dC or dC). The gel electrophoretic separation of the partial products was carried out as described[18], with the following slight modifications: the gel (30 × 80 cm) was the same composition as that shown in Fig. 1; the samples were loaded in 5 mM Trisborate, 7 M urea, 0.1 mM EDTA, 0.05% bromphenol blue and xylene–cyanol FF, and 20% sucrose; the top buffer compartment contained 7 M urea; the gel was pre-run for 16 H at 1 kV, and electrophoresis was for 24–48 h at 1.3–1.8 kV. Autoradiography was for 7–21 d at −20 °C. The prefix d for deoxy has been omitted.

Oligo- or poly(U) has not been found previously in the messenger strand of any virus, although it seems to be present at the 5′ end of the poliovirus minus strand[26], where it functions as the complement of the poly(A) on the opposite (plus) strand. It is not known whether oligo(U) has a special function in C997, nor whether it is present in other C serotypes. We have not detected

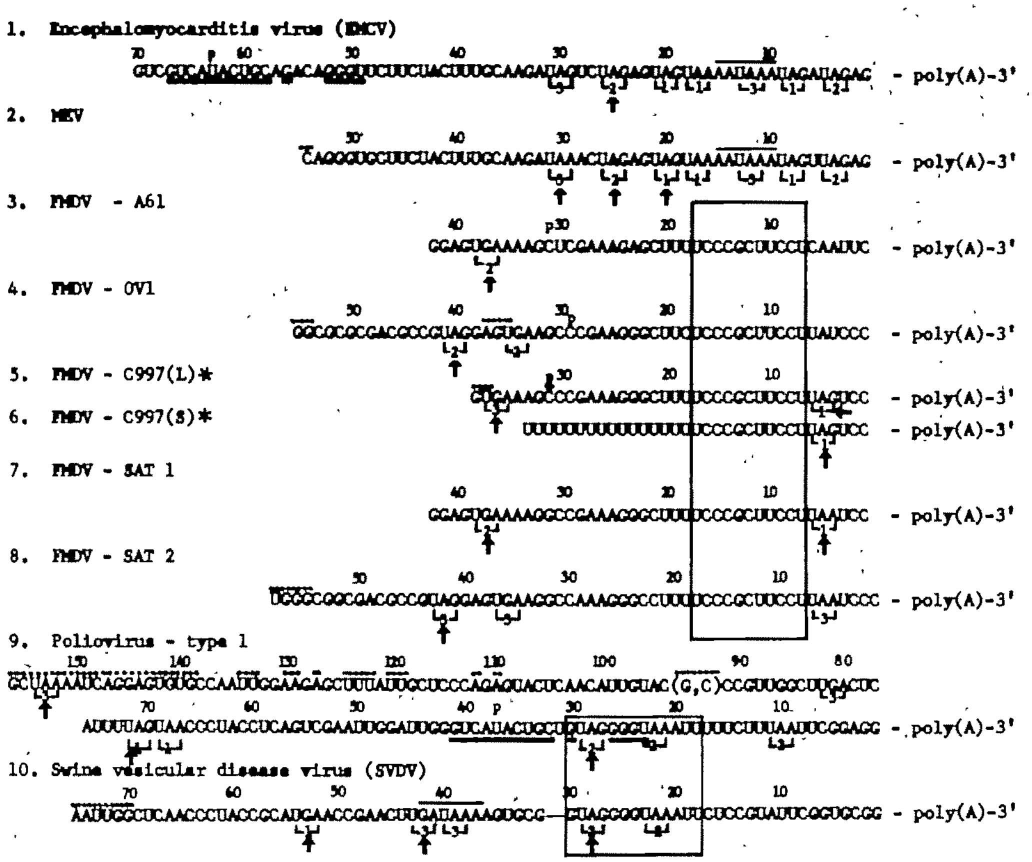

Fig. 3 3'-Terminal sequences of nine picornavirus RNAs. The sequences were deduced from the band patterns on the gels (Fig 2). Slight uncertainties are indicated by a dotted line. In the enteroviruses and FMDVs, the highly conserved areas are boxed in. A thick line draws attention to the homology between poliovirus and EMCV RNA. A thin line shows the sequences AAUAAA and GAUAAA. The letter p indicates palindromic sequences. Nonsense triplets are bracketed, and the protein synthesis reading frames in which they occur are indicated. Arrows point to potential termination codons of the coding region. Note that in EMCV the single potential termination codon was assigned from the positions of the other nonsense triplets in the sequence of 129 nucleotides next to the poly(A) (ref. 17). *L and S refer to sequence derived from large or small cDNA

oligo(dA) in the cDNA transcribed from the RNAs of four other FMDV serotypes, although the possibility of its presence in poorly transcribed cDNA cannot be ruled out.

There is considerable conservation of 3'-terminal sequences within the cardiovirus and FMDV groups (Fig. 3). The two cardioviruses are $>90\%$ homologous in the 54 nucleotides next to the poly(A). The five FMDV serotypes are $\sim75\%$ homologous in the 20 nucleotides next to the poly(A), and this includes a highly conserved sequence of 11 consecutive nucleotides, which is indicated in Fig. 3. Excluding the RNA corresponding to C997(S) cDNA, all five serotypes of FMDV also show $\sim75\%$ homology in the 38 nucleotides next to the poly(A). In this region, a purine-rich sequence (20 nucleotides) precedes a pyrimidine-rich sequence (20 nucleotides), suggesting that stable secondary structure could exist. For example, in the A61 strain, nucleotides 16–24 paired with nucleotides 29–37 would give a thermodynamically stable structure ($\Delta G \approx -8.4$ kcal mol^{-1}) (ref. 27). No such structure is likely in the C997 RNA species containing oligo(U), in which the 3'-terminal 33 nucleotides are almost entirely pyrimidines. There is, however, an opportunity for an alternative secondary structure in this RNA in which the oligo(U) pairs with the poly(A). The serologically unrelated enteroviruses, poliovirus and swine vesicular disease virus, are $>60\%$ homologous in the 71 nucleotides adjacent to the poly(A). Figure 3 draws attention to a highly conserved region in these virus RNAs. In SVDV, nucleotides 25–35 could pair with nucleotides 54–64, giving a highly stable double-stranded region[27] ($\Delta G \approx 12.0$ kcal mol^{-1}) in which seven out of 11 nucleotide pairs are GC. Only a marginally stable secondary structure could exist, however, involving the corresponding sections of poliovirus RNA.

Homologies between viruses from different genera are much less frequent. Figure 3 indicates one significant homology between poliovirus and EMCV, in which 15 out of 19 nucleotides are identical, between positions 49 and 67 in EMCV and positions 23 and 41 in poliovirus. It is interesting that much of the homologous region has the same nucleotide sequence when read in either direction[17] (a palindrome). 11- or 13-nucleotide palindromes are also present in the RNAs of the FMDV strains A61, OV1 and C997, centred at or near position 30. Palindromes have been found previously in the 3'-untranslated regions of host mRNAs from several different sources[24,28–30], and it has been suggested that they may provide binding sites for oligomeric proteins in the corresponding DNA[31]. However, this cannot be the case for the picornaviruses, which do not go through a DNA intermediate in their replication.

In conclusion, the presence of many nonsense triplets near the 3' terminus of some picornavirus RNAs, the absence of the putative signal AAUAAA in viruses from two genera and evidence of oligo(U) in a fraction of RNA from one virus, are all unexpected findings in the picornavirus genome. As expected, at least part of the 3'-terminal region in all picornavirus RNAs so far studied is not expressed into protein. It is possible that this untranslated portion has a special function, for example, to bind the virus polymerase complex during initiation of replication. Support for the idea that the 3' end may be specifically recognised comes from our finding that extensive sequence homologies exist in the RNAs of viruses within each picornavirus genus, whereas viruses from different genera show little similarity. These findings also strongly support the accepted scheme[15] for the division of picornaviruses into genera.

We thank Dr N. H. Carey for valuable discussions, Dr A. J. Hale for provision of research facilities and Dr M. Smith (University of British Columbia, Canada) for supplying p(dT)$_{10}$dG.

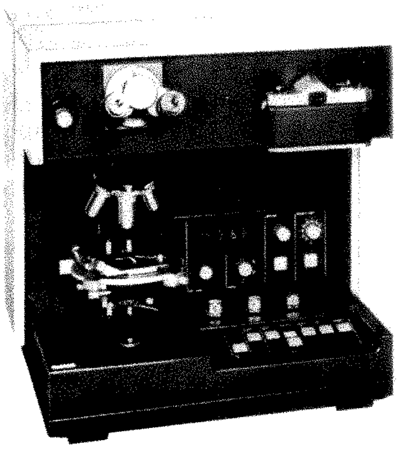
We've made life easier for the busy biochemist.

"For swift and accurate quantitative cell information, the GN5 Integrating Microdensitometer is a real discovery," she declared. "It makes cell study much easier and far outstrips manual methods."

Start to reduce your work load by asking for technical literature on the GN5. Use the journal reply system or call us, Barr & Stroud Limited, (Dept. N3),
Melrose House, 4-6 Savile Row, London W1X 1AF.
Telephone: 01-437 9652. Telex: 261877.

The GN5 Integrating Microdensitometer.

Accuracy and speed are perhaps the greatest benefits the compact and reliable GN5 brings to the analysis of your cell preparations. Scans are of only 4 second duration yet give 0.25 micron resolution. For histochemical and cytochemical studies, accuracy is better than ± 1% over an optical density range of from less than 0.1 to greater than 2.5. And there are other important features, including area measurement, electronic masking and narrowband illumination. A remarkably fine addition to your laboratory, and ergonomically designed to ensure that it is a comfortable one too.



Barr & Stroud

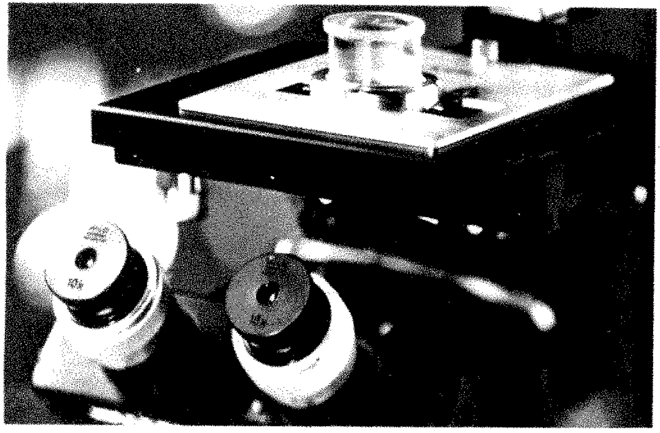
Wild M40 – the simple, direct way.



Investigations in vitro.

Laboratory vessels, Erlenmayer flasks, tissue culture chambers and Terasaki chambers are placed directly in the beam path of the Wild M40 inverted microscope. Liquids, sediments, precipitates, solution processes, crystal formation, culture growth and chemical reactions can therefore be readily observed.

The controls are conveniently low slung, and there is a six-place nose-piece. The base, the drive housing and the optics carrier form a single rigid unit which imparts the necessary stability to the instrument. The rich variety of interchangeable accessories enables the instrument to be expanded for cytology, bacteriology, immunology, environmental studies, chemistry etc. The information is in brochure M1 140e.

DNA sequence of the bacteriophage λ *c*I gene

THE *c*I gene of bacteriophage λ codes for the λ repressor. This protein is both a positive and a negative regulator of gene transcription (see ref. 1 for review). These functions are mediated by the interaction of repressor with two operators in the phage DNA. Both the nucleotide sequence of the λ operators[2-5] and the amino acid sequence of the λ repressor have been determined[6]. The ability of the λ repressor to bind operator DNA is greatly reduced by a proteolytic cleavage which occurs, for example, during *recA*-dependent prophage induction in *Escherichia coli*[7]. A single mutation (λ*c*I *ind*$^-$) prevents this cleavage and inactivation of repressor[7,8]. I present here the nucleotide sequence of the λ *c*I gene and identify the base change responsible for the ind$^-$ phenotype of λ repressor.

Restriction endonuclease fragments containing *c*I DNA were isolated either from phage λ DNA or from the plasmid pKB252 (ref. 9) by gel electrophoresis[10], and were end-labelled and sequenced by the chemical method of Maxam and Gilbert[11]. A partial restriction map of *c*I and surrounding DNA, and the positions and strands of sequenced restriction fragments are shown schematically in Fig. 1. Restriction fragments have been aligned by direct DNA sequence overlaps. The nucleotide sequence of *c*I and the amino acid sequence of the λ repressor[6] are shown in Fig. 2.

The sequence 5′ CCAGG 3′ occurs twice in the sense strand of *c*I DNA (bases 99–103 and 529–533) The second cytosine in this sequence is normally present as 5-methylcytosine in wild-type strains of *E. coli*[12,13]. As 5-methylcytosine fails to give a band in the chemical DNA sequencing method[11,14], its location is usually deduced by the presence of a characteristic gap in the pattern of bands, combined with sequence analysis of the complementary DNA strand. The presence of 5-methylcytosine at base 100 of the *c*I sequence was confirmed by these methods. The assignment of base 530 as 5-methylcytosine relies on a comparison of the protein and DNA sequences. The DNA sequence read from the sequencing gel was 5′ GAG C_{530}A GGT 3′, whereas the corresponding λ repressor sequence is Glu^{175}-Pro^{176}-Gly^{177}. The genetic code requires that proline be coded by a CCN codon, and therefore I assume that base 530 is present as 5-methylcytosine. Bases 102 and 532 of the *c*I antisense sequence are also present as 5-methylcytosines. In the *lacI* gene, 5-methylcytosines have been identified as hot spots for spontaneous and 2-aminopurine induced mutagenesis[15].

The DNA sequence of *c*I (Fig. 2) confirms the amino acid sequence determined for λ repressor by independent protein-sequencing methods[6]. The nucleotide sequence also agrees with the partial sequences determined previously for the 5′ and 3′ termini of *c*I[4,5,16] and for the 5′ sequence of *c*I mRNA transcribed from the P_{RM} promoter[1,16].

The *ind*$^-$ *c*I mutation was sequenced from the *Hinf*/*Eco*RI* 199-base-pair fragment (Fig. 1) isolated from phage λ DNA carrying the mutant allele. *ind*$^-$ *c*I DNA has an A at base 352 replacing the wild-type G. This base change generates an additional *Hin*dIII recognition site at bases 352–357 of *c*I. The presence of this additional restriction site in λ*c*I *ind*$^-$ DNA has been noted elsewhere[17]. The *ind*$^-$ base change occurs approximately halfway through *c*I, a position which correlates extremely well with its location in the genetic map constructed by Lieb[18]. In *ind*$^-$ λ repressor, a lysine should replace the wild-type glutamic acid at amino acid 117. The mutant repressor is thus considerably more basic than the wild type in physiological conditions.

The codon usage for wild-type *c*I is given in Fig. 3. Overall, there is a slight preference for T and A in the third base of the codons. However, the third position distribution is biased by the 11 codons in which G is obligatory (ATG and TGG) and the 50 codons for Lys, Glu and Gln which require either an A or G in the third position. In those triplets where any of the four bases is acceptable (CTN, GTN, TCN, CCN, ACN, GCN, CGN and GGN) there is a marked preference for T (38.6%) and a discrimination against G (10.9%) in the third position.

Fig. 1 Partial restriction map of *c*I and surrounding DNA. Restriction sites used for DNA sequence analysis of *c*I are indicated. Not all sites for *Eco*RI*, *Alu* and *Hha* are shown. The hatched areas in the lower scheme indicate the extent of reliable DNA sequence information from particular restriction cuts. Restriction fragments were 5′ labelled with [γ-^{32}P]ATP and polynucleotide kinase[11], and were cut with a second restriction enzyme. All sequencing is thus 5′→3′. The upper strand is the *c*I sense strand.

now you can measure testosterone and dihydrotestosterone separately or together

Our new RIA kit is the simplest and fastest available for the assay of testosterone and dihydrotestosterone, separately or together in research applications in a wide range of biological samples.

To assay both androgens together a high specific activity tritium label gives the assay a very sensitive detection limit of 3 pg dihydrotestosterone per incubation tube. Also, a wide range of concentration levels can be assayed, up to 400 pg testosterone and 800 pg dihydrotestosterone per incubation tube.

Separation of the two androgens is achieved without the need for column chromatography by the use of a novel oxidation step which destroys the testosterone present. The assay of the unaffected dihydrotestosterone is achieved with a simple protocol incorporating a short incubation time of 2½ hours. Standards for both androgens are provided. Accurate results are obtained easily and quickly.

new testosterone/dihydrotestosterone RIA kit

New Books in Neuroscience and Neurology

Maturation of the Nervous System

edited by M.A. CORNER, R.E. BAKER, N.E. VAN DE POLL, D.F. SWAAB *and* H.B.M. UYLINGS

PROGRESS IN BRAIN RESEARCH, Volume 48
1978 xii + 425 pages US$ 71.25/Dfl. 160.00 ISBN 0-444-80036

An authoritative and up-to-date review, this work reflects the most exciting developments in a rapidly growing area of neuroscience. The topics dealt with include:- specificity in synaptic innervation patterns, a survey of the central nervous system, determinants of neuronal development, hormones and hormonal effect on nervous system maturation and early development of behaviour.

Characteristics and Function of Opioids

edited by J.M. VAN REE *and* L. TERENIUS

DEVELOPMENTS IN NEUROSCIENCE, Volume 4
1978 xxii + 516 pages US$ 60.00/Dfl. 135.00 ISBN 0-444-80076-x

Published only one month after the conference, this book provides an authoritative insight into the functional significance of endorphins, and reflects the growing awareness of their role in mental illness. It also reviews the classical opioids, their specific effects and their interference with biological functions.

Senile Dementia: A Biomedical Approach

Proceedings of the Conference held in St. Louis, Missouri, March 22-23, 1978.

edited by KALIDAS NANDY

DEVELOPMENTS IN NEUROSCIENCE, Volume 3
1978 332 pages US$28.00 (fixed)/Dfl. 64.50 ISBN 0-444-00271-5

This unique book, the result of a Conference geared for both the researcher and clinician, covers basic neuroanatomical, neurochemical and neuroimmunological changes associated with aging. In addition, it gives extensive coverage to neuropathology, clinical manifestations, cerebral hemodynamics, electroencephalography, therapeutic and nutritional aspects of senile dementia.

Peripheral Neuropathies

Proceedings of the International Symposium held in the University of Milan, Italy, 26-28 June, 1978

edited by N. CANAL *and* G. POZZA

DEVELOPMENTS IN NEUROLOGY, Volume 1
1978 xii + 516 pages US$ 64.50/Dfl. 145.00 ISBN 0-444-80079-4

This authoritative book is the result of an international workshop of over 180 distinguished scientists of various disciplines. Topics covered include: axonal transport; neuropathies in chronic renal failure; compression neuropathies; diabetic neuropathies; metabolic and genetic neuropathies; basic problems in peripheral nerve pathology.

This multidisciplinary review of recent developments in a subject central to many areas of research will be of great value to neurologists, pathologists, anatomists, orthopaedists, diabetologists, and nephrologists.

New ecology exhibition at BM

Peter D. Moore

Introducing Ecology. British Museum (Natural History) Exhibition. *Nature at Work.* By British Museum (Natural History). Pp. 96. (Cambridge University Press. Cambridge, 1978.) Hardback £6.50; paperback £2.50.

AFTER about fifty years of conceptual evolution, the idea of the ecosystem, involving close relationships between the living and non-living world, is finally having an impact at the level of elementary biology teaching This is very welcome, for it may result in a more precise understanding of the fundamental basis of modern ecology and restore some meaning to the very term. The exhibition recently launched at the British Museum (Natural History), together with the associated book, will certainly serve to encourage this laudable trend.

The exhibition and the book concentrate on the energy relationships of ecosystems, which has the advantage of providing a unifying theme for the concepts portrayed but which inevitably results in the neglect of other interesting aspects of ecosystem study. Unity and flow, however, are vital if the interest of a visitor is to be maintained and this is certainly achieved. But energy is not easily conceived, an early display tries to overcome this by encouraging the observer to turn a wheel on the exhibit with sufficient gusto to generate the electricity for lighting the panels. Great fun for young children, but I wonder whether it really helps with their thermodynamics?

Energy movement through ecosystems as a theme also generates the problem of how to explain photosynthesis, the primary level of energy conversion. Here the exhibition and the book are at their weakest. and understandably so. One is left with two options: either you try to explain the complex mechanism of photophosphorylation or you leave photosynthesis as a black box with sunlight going in and energy-rich foodstuffs coming out. In fact the former course was chosen. Chloroplast structure is explained in some detail and the production of ATP and NADH is mentioned. but chlorophyll itself remains something of a black box. It is rather strange that this degree of biochemical detail is used at this stage when no equivalent account is given of respiration, a process just as vital to an understanding of energy flow. Also, as the emphasis throughout is on the presentation of concepts in a simple, pictorial fashion, is there any need to introduce such technical terms as autotrophs, heterotrophs, or even carbohydrates? Many of the weaker brethren my stumble needlessly at this first hurdle.

One of the unfortunate consequences of the energy flow concept from the botanical point of view is that the plant is reduced to the level of an energy conversion and storage system on which the rest of the (far more interesting) organisms depend. When photosynthesis has been dealt with, plants can be set on one side. Admittedly, some attempt is made to show the influence of climate and soil conditions on plant growth, but this display is difficult to follow because of its complexity.

From this point onwards, the quality of both exhibition and book begin to rise. The ways in which consumer organisms make a living are described and attention is drawn to the energy which their way of life demands in such activities as seeking food. Two habitats are considered in detail: an oak woodland (in which some taxonomic confusion over the species of oak involved is evident) and a rocky seashore (in which *Fucus serratus* is found above *Pelvetia canaliculata*). In dioramas of these habitats, the student is presented with such problems as working out food webs. In the book the answers are supplied at the end, but in the exhibition electronic links can be made between different organisms which results in a red or green light appearing, depending on the likelihood of one consuming the other. Observations on secondary school children operating this display suggested that many were unaware of the implications of the red or green light but this, I suppose, its one of the problems which educationists have to face.

Decomposition is tackled in a novel and effective way using animated flicker cartoons which are operated by the observer. The consequent recycling of elements is not fully dealth with at present, but I gather that a display of the carbon cycle will be added to the exhibition later.

Perhaps the most ambitious and, in my view, the most successful aspect of energy flow to be considered is the energy pyramid and ecological efficiency. Those students who have worked their way this far without losing the thread are presented with such fascinating questions as why carnivores may be more efficient than herbivores, and why the pyramid of biomass in aquatic systems is an inversion of that found on land.

Watching children in the exhibition one soon comes to the conclusion that the most popular exhibits are those with which they can interact, where questions are asked, choices made and buttons pressed. In this respect a new dimension is attained at this exhibition. Having completed the exhibition circuit, the student meets a computer console and screen with which he can tackle an ecological question. A problem is set up by the computer, such as what factors control winter moth caterpillars in oakwoods. Several alternative solutions are presented and the operator makes a choice which results in the presentation of data either supporting or negating the selection. Rejection of that hypothesis then returns the student to the initial choices The game provides a unique opportunity for a student to work his way through an ecological problem in a systematic and scientific fashion

Presentation of material in both exhibition and book is clear, graphic and caricatured, sometimes to the extent of being bizarre This will offend the purist But whatever the dusty academic may think of this venture, the fact remains that on the one hand a seven year old child may find the demonstrations rivetting in their overt appeal and on the other there are questions raised here which still occupy the minds of research workers. The potential spectrum of interest is vast and the message is clear and basic, that ecology has moved beyond natural history and has become a unified science through the development of such concepts as energy flow. ☐

Peter D. Moore is Senior Lecturer in Ecology at King's College, University of London, UK.

Embryological cookery book

Methods in Mammalian Reproduction. Edited by J. C. Daniel. Pp. 566. (Academic: New York, San Francisco and London, 1978.) $39.50; £25.65.

TEXTS that tell you how to do things, whether they be cookery books or manuals of bee-keeping or motor-cycle maintenance, can be valuable both for the experienced and for the novice; they also have a particular fascination for the voyeur, who has no intention of actually keeping bees or maintaining motor-cycles, but likes to identify with the contortions of those who do. Even the best of such books can be dangerous, however, if they are accepted as an alternative to visiting the master, watching him perform, and then trying the procedure yourself under his critical eye.

With this caveat, *Methods in Mammalian Reproduction* is warmly to be welcomed. Its predecessor, *Methods in Mammalian Embryology,* which appeared in 1971 with the same editor but a different publisher, must have achieved an extremely high average Citation Index rating; my own copy is constantly borrowed. The present volume has a very similar mix of 'developmental' and 'reproductive' topics to the previous one, despite its title, but the themes are now a little more sophisticated. For example, induction of ovulation has been succeeded by *in vitro* oocyte maturation, fertilisation by parthenogenesis, aggregation chimeras by injection chimeras.

Most of the book is concerned with embryos and the remarkable things that can be done to them during the pre-implantation period (oocyte maturation, experimental parthenogenesis, manipulation of ploidy, injection chimeras, immunological interference with development) or subsequently (embryo culture during and after implantation, embryo grafts to the chick, limb regeneration). Others describe techniques that can be applied more generally during development (freezing, tissue separations, one- and two-dimensional gel electrophoresis, and fluorography). Then there are chapters on particular groups of animals (marsupials; primates; embryo culture in rabbits, sheep and cows; embryo transfer in farm animals). Finally, there are a few rather heterogeneous chapters on the maternal side, dealing with pheromones, experimental delay of implantation, female genital tract secretions, intra-uterine devices in monkeys and rodents, grafting endometrium to ectopic sites, laparoscopy (not in humans) and amniocentesis (only in humans).

Some chapters are long and very detailed: gel electrophoresis; injection chimeras; amniocentesis, including cell culture and chromosome banding. Some read more as interesting accounts of rather esoteric research fields than as descriptions of widely used techniques: endometrial transplantation; immunological inhibition of development (mainly with antisera against zona pellucida); regeneration of mammalian limbs (they don't, even with electrical stimulation, but bits of brain implanted in the stump help, and bone, muscle and nerve individually do quite well).

Bibliographies are satisfactory only up to 1976, with some 1977 papers listed as being in press; the descriptions of some rapidly advancing areas, such as the use of ultrasound and amniocentesis in prenatal diagnosis, tend in consequence to be a little dated. Editing could be improved: for example, techniques for the recovery of embryos from monkey reproductive tracts are distributed among three chapters, laparascopy, IUDs, and primates; no cross-references are given. The index is inadequate.

These are minor criticisms. If you have found Joe Daniel's *MME* useful, you will want to possess *MMR* also. The initial purchase price is high, but you are likely to recoup it many times over, by increased efficiency, avoidance of costly errors, and some appreciation of what you may be letting yourself in for.

Anne McLaren is Director of the MRC Mammalian Development Unit, London, UK.

Dioxin workshop

Dioxin: Toxicological and Chemical Aspects. Edited by F. Cattabeni, A. Cavallaro and G. Galli. Pp.222. (SP Medical and Scientific Books/Spectrum: New York and London; 1978.) Distributed by Halsted/Wiley. £14.50; $26.50.

ON 10 July, 1976 the north Italian town of Séveso was contaminated with the discharge from a chemical reactor used for the manufacture of trichlorophenol. The discharge consisted primarily of sodium trichlorophenate, but also contained an extremely toxic by-product of the reaction 2,3,7,8-tetrachlorodibenzodioxin (TCDD).

Faced with a serious pollution problem the Province of Milan and the Lombardy Regional Government sponsored a workshop in October 1976 to which scientists working on polychlorinated dibenzodioxins (PCDDs) were invited. This book records the workshop proceedings.

Research on the toxicology of the PCDDs has increased at an exponential rate since 1976 Recently published results, for example, have shown, that TCDD will cause tumours in experimental animals. As the workshop proceedings contain no discussion of the potential carcinogenicity of the dibenzodioxins and make only cursory reference to mutagenicity studies, its coverage of the toxicology of these compounds is incomplete.

That section of the book dealing with the chemistry is, nevertheless, useful. Accounts are given of methods currently in use for the analysis of environmental samples containing PCDDs by various combinations of gas liquid chromatography, mass spectrometry and mass fragmentography; and there is some discussion of the problems encountered in separating dibenzodioxins from other industrial pollutants (for example, polychlorinated biphenyls).

But perhaps of most interest will be the information on decontamination methods following TCDD pollution. Both incineration and photolysis are considered. Temperatures in excess of 800 °C are necessary for the destruction of TCDD—at lower temperatures (300–500 °C) more of the dibenzodioxin is formed from precursors of TCDD and 2,4,5-trichlorophenate.

The processes of photolysis are covered in four separate chapters. In the presence of a hydrogen donor such as methanol, ultraviolet irradiation of TCDD will selectively remove chlorine atoms from the molecule, thus rendering it less toxic. Alternative solvents/hydrogen donors are required for field conditions, and the action of two such combinations (ethyl oleate and xylene, olive oil and cyclohexanone) is described. Results reported from field trials at Séveso suggest that the olive oil/cyclohexanone method effectively promotes the degradation of TCDD, and that little of the dibenzodioxin was leached into the soil, despite heavy rain during the experiment.

Two potential decontamination methods not referred to are chlorinolysis and bacterial action. Their omission is not particularly serious; however, as bacteria are probably responsible for the detoxification of most of the TCDD in the environment these are organisms which cannot be ignored.

On the whole the book should prove useful as an introductory text for students of the dibenzodioxins.

Programs of the Brain

J. Z. Young

J. Z. Young shows in his new book how our lives are governed by programmes written in our genes and brains. 'Fascinating and refreshing . . . . J. Z. Young is a rare phenomenon. Let us be grateful to him for pointing the way to a new synthesis and for sharing with us the reflections of a brain which is not only formidably furnished with knowledge, but powerfully and originally creative.' Anthony Storr in the *Sunday Times*. Illustrated £5.95

Man and the Stars

Hanbury Brown

This book sets out to show that astronomy has always been relevant to practical matters, and that the results are important, and familiar to us all. 'This is a thoughtful, amusing, and attractive book that should do much to encourage a rounded and broadminded approach to science, rightfully placed in its human context.' *New Scientist*. Illustrated £5.95

Neutron Stars

J. M. Irvine

No subject calls on a wider range of physics for its interpretation than the study of neutron stars – complex problems in magnetohydrodynamics, the properties of dense matter in the presence of large electromagnetic fields, the physics of materials, nuclear stability, superfluid hydrodynamics of a cold nucleon fluid, supernuclear densities, and the possibility of several new phases of matter, the general relativity theory of rapidly rotating objects, and gravitational collapse. This book gives a complete account for graduate students of the physicist's approach to predicting the structure and properties of neutron stars. £7.95 *Oxford Studies in Physics*

Large amplitude vibrations in molecules

Internal Rotation and Inversion: An Introduction to Large Amplitude Motions in Molecules. By D G Lister, J N Macdonald and N. L. Owen. Pp 246 (Academic: London and New York, 1978.) £11 50.

Large amplitude low frequency vibrations comprise a somewhat specialised topic within the subject of molecular vibration–rotation spectroscopy. However, they comprise a topic of particular interest for a number of reasons and are thus a deserving subject for a specialist text. The interest arises because these vibrations represent motions along the valleys in the molecular potential energy surface, so that they are of especial interest in the molecular dynamics of conformational changes and chemical reactions. Also, the experimental data on the energy levels of low frequency vibrations may be extensive (in contrast to the usual situation for other vibrations), and the theory by which they are related to the potential energy surface does not fall into the usual pattern of vibrational theory Thus, in principle a book on this subject might be of interest to a wide range of chemical physicists.

This book starts with an introductory chapter on the concept of large amplitude vibrations, with many examples, and diagrams of sections of potential energy surfaces. Chapter 2 deals with basic theory, chapter 3 gives a cursory account of experimental methods (microwave, infrared, Raman and NMR spectroscopy, and electron diffraction), chapter 4 reviews *ab initio* and semi-empirical potential surface calculations, and the remaining five chapters discuss particular examples of large amplitude vibration in more detail—essentially internal rotation, inversion and ring puckering vibrations, and conformational motions in macromolecules.

Although the physical ideas are well presented, the authors have attempted to write a book which is not too taxing in mathematical theory and quantum mechanics Sympathetic as I am to this ambition, the serious student has to face up to the theory, for indeed the relationship of experimental spectra to potential surface should be the unifying theme of the subject. Thus, I found the book weak in the very area where I feel it should be strong. The theory is loose where the student wants rigour; the material is badly organised; some important topics are not mentioned and others are discussed twice in different places without any apparent correlation. As examples of these defects: on p23 "transpose" should read "conjugate transpose"; equation (2.45) on p42 lacks a factor $\hbar^2/2I$, different methods of solving the Mathieu equation are discussed on p42 and p111 without any cross reference or comments to help the reader; and the effects of inversion on rotational constants are also discussed twice, on p58 and p70, again without cross reference (why is a first power term in x included on p70 and not on p58?), although one might reasonably have expected to find this discussion in chapter 7 or chapter 8. Many passages give me the impression that they will be of little help to a student who does not already know the subject, and of even less help to the student who does; as examples of this, consider the page about Van Vleck transformations (p25–26), or the four pages about gas electron diffraction (p81–84). The important topic of the symmetry of non-rigid molecules, developed in the past ten years by Longuet-Higgens, Hougen, Bunker, and others, does not seem to be mentioned anywhere in the book. Quasi-linear molecules are an important class of molecules with large-amplitude vibration that are not discussed.

The book has its good points; one of them is indeed the subject itself! But in today's sophisticated and competitive world of specialist scientific textbooks, I feel that it has not been written with the care and attention to detail that are necessary for success.

Ian M. Mills

Ian M Mills is Professor of Chemistry at the University of Reading, UK.

Thin films and the electronics industry

Thin Films: Interdiffusion and Reactions. Edited by J. M. Poate, K N. Tu and J. W Mayer. Pp.578 (Wiley: New York and Chichester, UK, 1978.) £25.

Many reasons are advanced to explain why our scientific and inventive abilities in the physical sciences are frequently not realised in industry. One good reason is the failure by scientists and industry alike to treat product design and manufacturing processes as vital technologies which must develop their own specialised sciences if inventiveness is to be fulfilled in the market. We all know, without effect, that this common neglect stems from our history when science developed rapidly and modern industry was founded, both occurring almost independently. This unsatisfactory division rooted in the scientist of independent means and the practical manufacturer has lead to the notions that the study of how one makes things and how they perform is too close to common work to be regarded as suitable activities for trained minds; and in any case such investment is wasteful Only during the last War did scientists effectively join with industry to develop expertise; but so quickly did we slip back that we now seem to have no defence against another crisis—that of market competition.

If one doubts the validity of these comments then it is only necessary to read recent views of the decision of the National Enterprise Board to enter the microprocessor field. Expert opinion on this relates to financial investment problems, preference for licencing overseas know-how, industrial need for microprocessors regardless of dependence on supply, and the novelty of the electronics and their social effects Nowhere have I found any mention of what must be done to found a satisfactory industry in the UK for the manufacture of large scale integrated electronics For example, who supplies the process plant? A new area of electronics cannot be established without the association of scientists and engineers developing production and product know-how and training skilled workers, that is, if the enterprise is to be more than a manufacturing unit with off-shore control of every aspect of its activities.

The book under review dealing with problems encountered in making and operating solid-state devices illustrates what must be done to establish such an industry It also shows how US companies are able to create the industrial science needed for the purpose at hand. There remarks are not intended to be disparaging of the work done by R & D scientists in solid-state laboratories in the UK but to point up the effects of inadequate R&D funding in an industry which once enjoyed a position next to the US in the world league.

The book's editors have experience of the subjects treated from research in their laboratories. Dr Poate, a one-time Harwell Fellow, is now with Bell Laboratories; Dr Tu is a specialist in solid-state diffusion at the IBM Thomas J Watson Research Center; and Professor Mayer is concerned with ion/atom collision effects at the California Institute of Technology. Their contributions are supplemented by others from research colleagues and members of the laboratories of Sandia and Philips (Amsterdam). These authors have related the thermal, chemical and electrical effects occurring in semiconducting devices to the materials and growth processes used in their fabrication. There are chapters on metal/metal interdiffusion, electromigration in thin films, electrode/compound substrate reactions, depth analysis and thin film deposition.

I read the chapters on atom transport and chemical reactions with interest because of their topical nature and because I was least well acquainted with their subjects. A new micrometallurgy is introduced in which the conditions for grain boundary diffusion, intermetallic and silicide formation and electromigration in a variety of film materials is treated over depth and surface dimensions of a fraction of a micrometer. As is essential in a book of this kind the text is well illustrated with micrographs.

I did not expect a detailed description of deposition techniques but a balanced and informed account of those in common use. Thus I question the wisdom of referring to ion beam deposition as a promising new technique while omitting mention of plasma chemical procedures which seem to have an important future in silicon technology. Also the reader is not informed that ion beam deposition is only possible when the self-sputtering yield of the incident ions is below one. Further, without experimental evidence it is unsatisfactory to suggest that ion bombardment may aid epitaxy; the case cited of poolycrystalline carbon is for deposition on a non-crystalline substrate. Generally, ion impact results in damage.

Sputtering is listed under collected deposition techniques as having the disadvantages of causing substrate damage and heating. Mention could have been made of sputtering apparatus with crossed electric-magnetic fields (magnetron) to deflect electrons from the substrate and reduce heating. It is an over simplification to lump together under "damage" particle and radiation effects which have different sources and intensities in sputtering plant operating from 10^{-3} to 10^{-1} torr gas pressure. The treatment of mixed component sputtering is not consistent. In the discussion of depth analysis (p149) it is said correctly that after an induction period components are released at rates proportional to their bulk contents, but on p95 it is stated that this only happens if there is no preferential sputtering to change the target surface composition. Few mixtures can have sputtering yields directly proportional to their contents but preferential sputtering raises the surface content of the less favoured component thereby aiding the latter's emission. As the emission of a component is proportional to the product of its surface content and sputtering yield, an equilibrium is reached under which the emission ratio is equal to the component ratio of the bulk material.

It is always dangerous to refer to a reference by way of another (in this case Chopra for Gillam) as on p95 when discussing the enriched Au layer formed on $AuCu_3$ alloy during Ar sputtering. The enriched layer is stable and results in component emission with the bulk contents ratio and not that of the enriched layer as stated on p95.

The above criticisms are of subsidiary material and they do not detract from the value of the main text in dealing with the behaviour of metal/semiconductor systems. As a reference work it will be of value to those who want to obtain a comprehensive picture of operational problems in solid-state electronics and also those who are entering the field to produce electronic devices. The authors and the Electrochemical Society (who supported the work) are to be commended for recognising its need and for its useful preparation.

L. Holland

L. Holland was director of R&D at Edwards High Vacuum, and is now responsible for the Unit for Plasma Materials Processing at the University of Sussex, UK.

Asiatic ungulates

Mountain Monarchs: Wild Sheep and Goats of the Himalaya. By George B. Schaller. Pp. 425. (Chicago University Press: Chicago and London, 1978.) £17.50.

This book, the latest in the generally excellent Chicago University Press series on wildlife behaviour and ecology, reports the results of three years of field work with the large mammals of the Himalayas, with emphasis on the wild sheep and goats of the region. The work will undoubtedly stand as the foremost source of information on these Asiatic ungulates for many years. One short chapter describes observations of the large carnivores of the region.

The book is generally organised into chapters dealing with broad biological topics such as distribution, physical attributes, herd dynamics and courtship behaviour. In each chapter, the array of species is treated according to the level of information available. Narrative or tabular summaries of the biological attributes of each species are generally lacking. This fragmented mode of presentation makes the work less readable than other books in the same series. The organisation of the book, together with its enormous geographical scope and the unevenness of information on various species, makes reading frustrating and confusing at times. Nevertheless, the author is to be commended for putting together in one volume the results of years of fieldwork under incredibly difficult conditions and an exhaustive review of the relevant literature, scanty though the latter is. Fortunately, the index is reasonably complete, although it cannot be depended upon to ferret out every piece of information, nor is it very helpful in dealing with the vast and confusing array of place-names.

The author concentrated his fieldwork on three species in Pakistan, Nepal and India: urial (*Ovis orientalis*), wild goat (*Capra aegagrus*) and bharal or blue sheep (*Pseudois nayaur*). The information on bharal is probably the most valuable and interesting. This little-known species possesses a complex mixture of sheep-like and goat-like behavioural and morphological characteristics. Schaller concludes (p44) that, "In general, bharal are considered aberrant goats, with sheep-like affinities". Again, however, the reader must refer to many pages of text, scattered throughout the book, to construct a cohesive picture of the biology of this species.

A concluding chapter on the evolution of the Caprinae provides a new perspective on this topic based on the author's own data on Asiatic caprids and literature review. This discussion of evolution and dispersal presents some counterpoints and alternative hypotheses to those of V. Geist (*Mountain Sheep*, Chicago University Press, 1971). Taken together, the two books provide a provocative basis for further research. However, as the author makes abundantly clear in his concluding remarks on the conservation of the Himalayan fauna, time is running out. Many species have been fragmented into small isolated populations, occupying habitats drastically altered by man. The reader is left with the clear impression that even the best system of reserves in the Himalayas will be inadequate unless broad changes in land-use practices can be instituted. In this regard, the enormity of the problems, economic, ecological and political, to be faced is evident.

ANALYSIS 79

Automation in Industrial and Clinical Chemistry

The next Analysis conference will be held at The City University, London on 16th-18th July, 1979.

This conference will focus attention on the cross-fertilization of ideas and concepts of automation between workers in clinical, industrial and academic environments.

Automation implies a system approach that can be applied at all levels of the analytical procedure and when applied in a complete sense has in addition to a technical and scientific impact an influence on managerial, organisational and economic considerations. The conference will focus attention on all these aspects within the general framework of the following sessions:

- Education
- New Instrumentation
- Costing and Management
- Applications
- Standardisation

The programme committee comprising Dr. Peter Stockwell, Dr. Fred Mitchell, Derrick Porter and Fred Fearn, have invited an international team of authoritative speakers to provide the keynote lectures and to chair the various sessions. Whilst the majority of speakers have been invited, there will be sessions for short, submitted papers. Authors wishing to present papers in these areas should submit abstracts for consideration by the programme committee before 30th November 1978.

For further details on Analysis 79 contact Beverly Humphrey, Scientific Symposia Ltd., 33/35 Bowling Green Lane, London EC1R 0DA. Tel: 01-837 1212.

Seed Pathology Volumes 1 and 2

Paul Neergaard

This is a unique and comprehensive compilation of the most recent data on the subject, brought together by an internationally recognised authority. It is the first book in this field and it is thoroughly up to date.
Paul Neergaard gives a comprehensive survey of research and current concepts relating to seed-borne diseases, the methods used for their identification and control, the mechanics of their transmission through seeds, procedures for laboratory seed testing, and the risk assessment of crop losses due to seed-borne diseases. The book will have a wide application both as a university textbook and as a practical guide and reference work for those involved in almost any sphere of the subject.

Contents

Volume 1 – Part 1: Pathogens – Diseases – Hosts – Economic Significance of Seed-Borne Diseases – Diseases and Injuries of Seed – Seed-Borne Viruses – Seed-Borne Bacteria – Seed-Borne Fungi – Seed-Borne Nematodes – Storage Fungi – Impact of Seed-Borne and Storage Fungi on Animal and Human Health – Types of Host in Relation to Types of Pathogen – Morphology and Anatomy of Seeds in Relation to Transmission of Pathogens.
Part II: Mechanisms of Seed Transmission – Introduction to Part II – Environment and Plant-Seed Infection – Entry Points of Seed Infection – Infected or Contaminated Parts of the Seed – Seed-Plant Transmission, Establishment of Infection and Course of Disease – Environmental Physicochemical Factors Affecting Establishment and Course of Disease – Environmental Biotic Factors Affecting Establishment and Course of Disease – Intermezzo – Factors Inherent in the Pathogen Affecting Establishment and Course of Disease.
Volume 2 – Part III: Principles of Control – Introduction to Part III – Seed Crop Management – Management of Seed Storage – Seed Treatment, Procedures and Equipment – Mechanism and Practical Use of Chemical Seed Treatment – Testing Seed Germicides and Treated Seed – Quarantine for Seed.
Part IV: Seed Health Testing Methods – Objectives of Seed Health Tests – Sampling – Examination of Ungerminated Seed – Incubation Tests 1: Procedures – Incubation Tests II: Factors Affecting Test Results – Bioassays and Biochemical Procedures – Inspection of Plants Beyond the Seedling Stage.
Part V: Assessment of Seed-Borne Inoculum – Forecasting Losses from Seed-Borne Diseases and Assessing Disease Tolerances for Seed Testing.

£60.00 for set of two volumes

APPOINTMENTS VACANT

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

(University of London)

Denmark Hill, London SE5 8RX

RESEARCH ASSISTANT

o work in Cardiac Research Labora-
ory in King's College Hospital (Dr D.
lewitt) Project involves assessment of
ew drugs designed to prevent
bnormal heart rhythms after coronary
hrombosis. The Research Assistant
vill be responsible for plasma drug
evel estimations. Experience of
pectrofluorimetric and gas chromato-
raphic techniques an advantage. First
legree in Biochemistry or Pharma-
ology or H.N.C. qualifications
equired. Salary according to age,
ualifications and experience. Further
letails may be obtained from Dr D.
lewitt, telephone 01-274 6222 Ext.
500.

Applications to the Secretary of the
ledical School at the above address.
lease quote reference EJ/N.

BRUNEL UNIVERSITY ASSISTANT LIBRARIAN

Applications are invited from uni-
ersity graduates with a degree in
cience or Engineering for the post of
ssistant Librarian in the University
ibrary. Candidates, preferably with
ibrary qualifications, should have an
nterest in computers and their uses
n libraries and information retrieval.

Salary within the national IIA range
3,910 to £7,754 (under review) plus
450 London Allowance.

Write for application form and
urther details to the Assistant Secre-
ary (Establishment), Brunel University,
xbridge, Middlesex UB8 3PH or
elephone Uxbridge 37188 extension 49.

Closing date: December 15, 1978.

8451(A)

IMPERIAL COLLEGE LONDON BIOCHEMIST/ NEUROCHEMIST

A Scientific Research Assistant with
or 3 years postdoctoral research
xperience is required for MRC
nded projects on cellular biochemi-
l aspects of the organisation and
nction of neurotransmitter systems
synapses in the mammalian CNS.
background in neurochemistry is not
strict requirement, but experience
ith incubating tissues, subcellular
action or affinity chromatography
ould be advantageous. The successful
ndidate would join a team of ten
orking on closely related topics.

The post will be available from
nuary 1, 1979 and would be renew-
le on an annual basis for at least 5
ars.

Salary would be commensurate with
perience. Applicants should send
rriculum vitae and the names of
o referees to Dr. H. F. Bradford,
epartment of Biochemistry, Imperial
ollege, London SW7 2AZ.

8492(A)

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF PHYSICS AND ASTRONOMY

Mullard Space Science Laboratory

HOLMBURY ST MARY
DORKING, SURREY

Applications are invited for a postdoctoral Research Assistantship financed by the Science Research Council for work on the analysis and interpretation of magnetospheric particle data obtained from the Laboratory's instruments carried on rockets and satellites, in particular two GEOS satellites. The appointment will be on a yearly basis for up to three years, commencing as soon as possible. Salary within the range £3,883 to £6,080 plus U.S.S. membership.

Applications, with curriculum vitae and the names of two referees, should be sent to Professor R. L. F. Boyd, C.B.E., F.R.S., at the above address.

8399(P)

BERKELEY PHYSICS

The Physics Department of the University of California, Berkeley, expects during the next two years to be making one or two appointments at the ASSISTANT PROFESSOR level. Preferred areas of research are astrophysics, atomic and plasma physics, condensed matter physics, nuclear physics, and particle physics, with some priority given to theoretical condensed matter physics, experimental plasma physics, and theoretical particle physics.

Applicants should write before February 1, 1979, to the Chairman of the Physics Department, University of California, Berkeley, CA 94720, USA, giving curriculum vitae, publication list, and references. The University of California is an Affirmative Action Employer.

8396(A)

Applications are invited for a

FACULTY POSITION IN ZOOLOGY

beginning September 1, 1979. Candidates are sought at, but not restricted to, the Assistant Professor level. Applicants should have a research background in structural–functional relationships at analytical ultrastructural, physiological, and biochemical levels, with emphasis on such areas as cell–cell interactions, cell motility, cell surface phenomena and/or membranes. Applicants should have sufficient breadth to be able to contribute to undergraduate teaching at the organismal level, as well as in their specialty.

Send application letter, statement of research plans, curriculum vitae, including teaching and funding experience, sample reprints, and names of five referees to: Dr A. G. Jacobson, Department of Zoology, University of Texas at Austin, Austin, Texas 78712.

Application deadline: December 15, 1978.

An equal opportunity/affirmative action employer.

8497(A)

NATIONAL COUNCIL FOR SCIENTIFIC RESEARCH

Applications are invited from suitably qualified persons for the following posts in Animal Productivity Research Unit and Food Technology Research Unit of the National Council for Scientific Research:-

1. VETERINARY PATHOLOGIST/MICROBIOLOGIST

To conduct research on diseases of genital systems (male and female) and other systems associated with fertility of cattle.

2. NUTRITIONIST

To conduct research in Livestock nutrition with special emphasis on developing balanced feeds for livestock from local agro-industrial by-products.

3. BIOCHEMIST/PHYSIOLOGISTS

To carry out investigation to obtain base-line data on the physiology of reproduction of local breeds of cattle. Experience in steroid essay is required.

QUALIFICATIONS: Basic veterinary qualification is required for the first post but would be an advantage for the other two posts. In all cases applicants must have a research degree and experience in their fields of specialisation. Detailed job descriptions are available on request.

4. FOOD ENGINEER

To participate in development of food processing technologies suitable for local conditions. To be particularly responsible for food process development studies at pilot plant level and to design simple college/village scale food processing equipments. Applicants must have a university degree in Food Engineering with considerable experience in research and development work in food technology and in design of simple food processing equipment.

5. FOOD SCIENTIST/TECHNOLOGIST

To conduct investigation on post harvest physiology of local fruits and vegetables with a view to developing appropriate storage methods; to develop suitable processes for production of processed products from local fruits and vegetables and other agro-industrial by-products.

Applicants should have senior research degree in food technology with considerable experience in Research and Development work on fruits and vegetables.

Detailed job descriptions are available on request.

Salary according to qualifications and experience will be on the following scales:-

Senior Principal Professional Officer K7,812 by 204 to K8,016 by 216 to K8,232.

Principal Professional Officer K6,756 by 216 to K6,972 by 228 to K7,200 by 204 to K7,608.

Senior Professional Officer K5,424 by 288 to K5,712 by 300 to K6,012 by 312 to K6,324.

Applications giving full personal details, qualifications and experience giving names and addresses of three referees should be submitted to:-

The Secretary General
National Council for Scientific Research
P.O. Box CH 158
Chelston
LUSAKA
Zambia.

8460(A)

WRITTLE AGRICULTURAL COLLEGE

LECTURER — Grade 1A or 1B

required as soon as possible in the Science Department to teach principles of crop protection and plant physiology to H.N.D. and O.N.D. courses in commercial and amenity horticulture.

Further details and application forms obtainable from:
The Principle, Writtle Agricultural College, Chelmsford, Essex CM1 3RR.

8456(A)

OVERSEAS DEVELOPMENT

KNOW-HOW: vital to developing countries

Rice Agronomist

Tanzania

Required to work in Southern Tanzania with responsibility for executing a rice research programme. Will be stationed at Naliendele Agricultural Research Institute and will provide the main source of professional advice on rice production with priority being given to the areas selected for inclusion in the Tanzania/British Joint Programme. Will be assisted by a Field Officer and two Field Assistants provided by the Ministry of Agriculture and will directly supervise their work. Will also advise on a suitable staff training programme, including in service and overseas training.

Appointment 2 tours of 1 year. Salary (UK taxable) in range £8,800 to £10,000 p.a. plus tax-free overseas allowance in range £1,400 to £3,570 p.a. (Ref. 331 X).

The post is wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowances other benefits normally include paid leave, free family passages, childrens education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.

For full details and application form please apply, quoting reference stating post concerned, and giving details of age, qualifications and experience to.

Appointments Officer,
MINISTRY OF OVERSEAS DEVELOPMENT,
Room 301, Eland House,
Stag Place, London SW1E 5DH. 8404(A)

ODM

HELPING NATIONS HELP THEMSELVES

POLYTECHNIC OF CENTRAL LONDON

BIO-MEDICAL RESEARCH GROUP

RESEARCH FELLOW (TISSUE CULTURE)

required to establish human retinal tissue cultures for research into inherited retinal diseases The Fellow will set up the facilities required to grow cell lines and will initiate and be responsible for subsequent research projects The successful candidate will have experience of tissue culture or cell biochemistry and proven ability to undertake independent work and to provide leadership

RESEARCH ASSISTANT (RADIATION PHYSICS)

required for a project on microdosimetry of the lung to investigate the potential hazard of inhalation of fine plutonium dust Since the alpha-particles from such material travel only short distances in tissue, it is possible that the local energy deposited will give rise to effects different to those arising from homogeneous irradiation. An initial study with the rat lung lends support to this idea and the work needs extending to the human lung

RESEARCH ASSISTANT (BIOENGINEERING)

required to work with a computer based instrumentation system for measuring the forces under the normal and pathological human foot The successful candidate will be a graduate with a good honours degree in Engineering or Physics, and would be expected to register for a higher degree

RESEARCH ASSISTANT (CLINICAL AUDIOLOGY)

required to work in cooperation with a London Teaching Hospital on the measurement of human auditory function. If appropriately qualified the appointee will be registered for a higher degree.

Salary scales: Fellow £4,149 to £4,440, Assistant £3,015 to £3,189

Application forms and further details from the Establishment Officer, P.C.L., 309 Regent Street, London W1R 8AL (Tel: 01-580 2020 ext 212) Closing date. December 7, 1978. 8441(A)

UNIVERSITY OF QUEENSLAND

Australia

DEPARTMENT OF MINING AND METALLURGICAL ENGINEERING

Applications are invited for the the post of

RESEARCH ASSOCIATE

to study phase transformations in inorganic materials with special reference to reactions of gases with metal oxides Research to be carried out under the supervision of Dr P. Hayes, will involve studies of both reaction kinetics and product morphology

Applicants should hold or be about to complete a Ph.D. in Metallurgy or Physical Chemistry, experience in computing and electron microscopy desirable.

Australian Research Grants Committee post available from January 1, 1979

Salary $A13,083 to $A14,987 Assistance with travel is available for successful applicant.

Applications with curriculum vitae and the names of two referees should be sent as soon as possible to: The Staff Officer, University of Queensland, St. Lucia, Queensland 4067, AUSTRALIA. Quote Reference No 38178 8490(A)

GRADE 3 Technician vacancy in an active protein chemistry research group The work involves the running and routine maintenance of sophisticated analytical instruments. Experience with automated amino acid analysers or other similar equipment would be an advantage. Salary in the range £3,153 to £3,525 (under review) including London Weighting. Write or telephone for an application form to Departmental Superintendent, Biochemistry Department, Imperial College, London SW7 2AZ. Telephone 589 5111, Ext. 1119. 8433(A)

MASS SPECTROMETER Engineer/Technician required to join the group of Dr H. R. Morris Applicants must have experience in mass spectrometer maintenance including electronics. The person appointed will join an active group interested in instrumental development and modification. Present equipment includes MS30 and MS50 spectrometers and a DS505M data system Interests include C.I., F.D., laser and moving belt developments. The appointment will be on Technical Grade 6 scale £4,119 to £4,830 (under review) including London Weighting

Write or telephone for an application form to Departmental Superintendent, Biochemistry Department, Imperial College, London SW7 2AZ Telephone 589 5111, Ext. 1119 8432(A)

Department of Oral Anatomy
ROYAL DENTAL HOSPITAL
St George's Hospital Medical School

Cranmer Terrace, London SW17

Electron Microscopy Technician Grade 5 required salary scale £3,186 to £3,720 plus £465 London Weighting. Experience in transmission electron microscopy and associated photography essential. Knowledge of scanning EM advantageous.

Applications with names of two referees to be submitted to Dr A. F. Hayward at the above address by November 31, 1978 For further information telephone 01-672 1255, Ext. 4633. 8411(A)

BRITISH ANTARCTIC SURVEY CAMBRIDGE

SENIOR SCIENTIFIC OFFICER/ PRINCIPAL SCIENTIFIC OFFICER

The BAS has a vacancy for a GEOLOGIST to be responsible for assessing the mineral potential of the Survey's operating area Applicants must be capable of identifying areas of interest from existing rock collections and from published and unpublished data The post involves original research, both in the field and the laboratory, to examine the origins and distributions of mineralised areas This will relate directly to geochemical, petrological and geochronological studies being made at present to understand the plate-tectonic evolution of the Gondwanian and Andean belts

Applicants must be prepared to visit Antarctica to carry out field-work, excellent health, therefore, is essential **Qualifications and Experience:** Candidates should have an honours degree or equivalent in geology, plus at least 5 years relevant experience **Salaries:** Senior Scientific Officer, £5,154 to £6,898 per annum, Principal Scientific Officer: £6,609 to £8,461 per annum Starting salary may be above the minimum, according to qualifications and experience.

The staff of the Council are not Civil Servants, but their pay and conditions of service are similar to those of scientists in the Civil Service. There is a non-contributory superannuation scheme

For further details and an application form (please quote ref BAS 105) apply to the Establishment Officer, British Antarctic Survey, Madingley Road, Cambridge CB3 0ET.

Closing date: December 11, 1978

THE NATURAL ENVIRONMENT RESEARCH COUNCIL

8495(A)

THE INTERNATIONAL CENTRE OF INSECT PHYSIOLOGY AND ECOLOGY

Nairobi, Kenya

Applications are invited from suitably qualified persons for the following positions:

1. RESEARCH SCIENTIST OR POST-DOCTORAL RESEARCH FELLOW (TSETSE POPULATION DIVERSITY PROGRAMME)

REF: SCI/78/24

Qualifications:

Ph.D. with 5 or more years post-doctoral experience in biological sciences and a demonstrable experience in ecological or eco-genetic research with anthropods. High quality research for Ph.D. and evidence for excellence since doctorate will be a distinct advantage.

Responsibilities:

The successful candidate will carry out research in the field of tsetse population dynamics.

2. RESEARCH TRAINING FELLOWSHIPS IN INSECT ECOLOGY (7 POSITIONS)

REF: SCI/78/25

Qualifications:

Young African Scientists, holding Ph.D. or M.Sc. degrees in entomology or zoology, with bias towards ecology. High quality research capability should be proven as evidenced by thesis, dissertation, or any other relevant research experience. Scientists completing thesis work from recognised universities are also legible. The positions will be available in 1979.

Responsibilities:

The successful candidates will undertake research in ecology of livestock ticks, tsetse, medical vectors or tropical diseases (especially mosquitoes and biting flies), stem and pod borers, African armyworm, harvester termites, and sorghum shootfly, collaborating with ICIPE research scientists who are mainly working in eco-physiological research.

Research training will be carried out mainly at the ICIPE Field Stations located in the coastal, semi-arid savannah, and lake-shore regions of Kenya. Further training in advanced ecological techniques may be implemented in Kenya and abroad as the individual cases may demand. Applicants should indicate their preference in research.

3. CONTROLLER FOR INSECTARY SERVICES—

REF: SCI/78/26

Qualifications:

Candidates should be in possession of a Ph.D. or M.Sc. degrees, preferably in insect or animal pathology, but possibly also in zoology, biology, or physiology. They should have strong technical training and a solid scientific or research background at a senior level. They should necessarily be interested in insect breeding problems and techniques.

Responsibilities:

The successful candidate will be required to (a) plan the insect and animal breeding unit; (b) carry out experiments needed to establish routines for the breeding of each of the target insect species and required laboratory animals; (c) supervise the operations of the insect and animal breeding unit; and (d) train staff working under him. It is expected also that he will monitor the health of insects under his care. It is hoped that the successful candidate will be able to commence work immediately.

GENERAL INFORMATION FOR ALL POSITIONS:

Salary:

Negotiable and include attractive benefits.

Applications giving detailed information or general education, professional qualifications, experience, marital status, age, present terms of employment (including salary), names and addresses of four referees (including one personal), and photostat copies of relevant certificates and diplomas should be addressed to:

Administrative Manager,
I.C.I.P.E.
P.O. BOX 30772,
NAIROBI.

to reach him not later than 20th December 1978.

8412(A)

unilever research

Pathologists

Due to expansion our Environmental Safety Division requires–

(1) One pathologist with experience.
(2) Two veterinary graduates interested in becoming pathologists

Successful applicants for these posts would be encouraged to commence or complete preparation for the membership examinations of the Royal College of Pathologists.

Our Environmental Safety Division employs almost 200 people whose prime job is to establish the toxicological safety of Unilever Products Pathologists do autopsies on small animals, make histopathological examinations and prepare reports. Staff are encouraged to undertake more specialised research in the field of toxicology/pathology

The division forms part of the Unilever Research, Colworth Laboratory which occupies a 1300 acre estate, ten miles North of Bedford.

Successful candidates will be eligible for BUPA and assistance with removal expenses.

Please write quoting Ref CH-200M and giving details of career history to:

Miss J. Kenny,
Personnel Officer,
Unilever Research,
Colworth Laboratory,
SHARNBROOK,
Bedford MK44 1LQ.

8429(A)

PHARMACOLOGISTS

Weddel Pharmaceuticals Ltd., a subsidiary of the Union International Co. Ltd., wish to recruit two PHARMACOLOGISTS for the Pharmacology Department at the Groups' Research Centre at St. Albans, Herts.

The work involves biological studies on naturally-occurring inhibitors of mitosis and expertise in oncology, immunology or haematology would be an advantage.

Applications are invited from Biological Scientists with a postgraduate degree and the ability to make a significant contribution to the output of an active, expanding department.

Please write, giving full personal and career details including present salary, to The Staff Manager (AD 6071) Weddel Pharmaceuticals Ltd., 14 West Smithfield, London EC1A 9JN. 8463(A)

AN FORAS TALUNTAIS

GRADUATE IN AGRICULTURAL SCIENCE OR VETERINARY SCIENCE

Required for research in cattle breeding at Belclare Research Station, Tuam, Co. Galway.

The appointee will be considered for a permanent post after an initial two years employment. Commencing salary will depend on qualifications and experience.

ESSENTIAL *either* an honours University Degree or equivalent in Agricultural Science *or* a degree in Veterinary Science or equivalent.

DESIRABLE appropriate post-graduate qualification and—or research experience.

Application forms and further particulars from Personnel Department, An Foras Taluntais Headquarters, 19 Sandymount Avenue, Dublin 4 (Phone (01) 688188). Latest date for receipt of completed entries is Thursday, November 30, 1978.

8402(A)

UNIVERSITY OF ESSEX

DEPARTMENT OF CHEMISTRY

CHAIR IN BIOLOGICAL CHEMISTRY

Applications are invited for a newly established Chair of Biological Chemistry in the Department of Chemistry for appointment from October, 1979 Preference will be given to applicants in one of the following areas enzymology, bio-inorganic chemistry or in the application of physico-chemical methods to biological systems

Applications (12 copies, quoting AG/56/N), including a curriculum vitae and the names and addresses of three referees, should reach the Registrar, University of Essex, Wivenhoe Park, Colchester CO4 3SQ, from whom further particulars may be obtained, by December 15, 1978

UNIVERSITY OF LEUVEN BELGIUM

RESEARCH ASSOCIATE in VIROLOGY

Applications are invited for the post of Research Associate, tenable until July 1980 with extensions up to 4 years possible, to assist in research mainly on basic aspects of viral hepatitis, but also on other subjects of medical virology.

Research experience in virology is necessary, and proficiency in biochemistry, immunology or electron microscopy would be important assets. The candidate should have a Ph.D. or M.D. with thesis, or equivalent credentials. A working knowledge of English is desired.

Salary is in the range of 19,000 to 33,000 US dollars per annum, depending on age and qualifications. It is indexed to the cost of living, and social provisions including health insurance are as for Belgian nationals.

The position is open immediately. Applicants are invited to submit now their curriculum vitae, list of publications, addresses of two referees, and the date at which they are free to: Professor J. Desmyter, Rega Institute for Medical Research, Minderbroederstraat 10, B-3000, Leuven, Belgium.

8394(A)

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF GENETICS

TECHNICIAN GRADE 5

A vacancy exists for a laboratory technician to join a small group investigating DNA repair and recombination mechanisms in the bacterium **Escherichia coli.** The person appointed will be expected to assist with research work and collate data for analysis, in addition to carrying out general laboratory maintenance.

Minimum qualifications H.N.C. or equivalent although a degree in an appropriate discipline would be an advantage. Preference will be given to candidates with previous experience in microbiology, genetics or biochemistry.

The position is funded by the S.R.C. and will be for a period of one year in the first instance.

Salary within the range of £3,186 to £3,720 per annum.

Applications in writing, stating age, experience, qualifications and the names of two referees should be sent to the Establishment Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Ref. No. GN/10/78. 8437(A)

CHEMIST/BIOCHEMIST

GENETICS RESEARCH UNIT

ROYAL CHILDREN'S HOSPITAL RESEARCH FOUNDATION

Flemington Road, Parkville,
Melbourne, Victoria 3052, Australia.

Position available in group studying inborn errors of metabolism for a Postdoctoral Scientist with experience in organic chemistry, biochemistry or neurochemistry and a particular interest in human biochemical genetics. Opportunity to develop own field of interest and to contribute to existing projects. Particular needs exist for development of new methods of detecting and identifying metabolites in body fluids and tissues. Expertise in intermediary metabolism, enzymology or protein chemistry also valuable.

Salary on Senior Research Officers scale of N.H. and M.R.C.—dollars A15,179 to A19,940 per annum.

Applications (in writing) or enquiries to Professor David Danks. 8415(A)

M.I.T.

Postdoctoral and Predoctoral Research Positions

Several positions are available for research in genetic toxicology with emphasis on mechanisms of chemical mutation of human cells. Strong background in chemistry is desired of predoctoral researchers, and molecular biology of postdoctoral researchers. Please send resumes to Professor William G. Thilly, Room E18-666, M.I.T., Cambridge, MA 02139. M.I.T. s an equal opportunity employer.

8392(A)

SIMON FRASER UNIVERSITY

BRITISH COLUMBIA, CANADA

DEPARTMENT OF BIOLOGICAL SCIENCES

ENTOMOLOGIST

The Department of Biological Sciences invites applications for a tenure track position in entomology. The successful applicant will be expected to develop a strong research programme and to participate in the teaching programme at both the undergraduate and graduate level including courses in the Master of Pest Management Programme. Candidate must have a Ph.D. degree in entomology or related subjects; preference may be given to individuals with teaching and research experience in agricultural pest management. The position is available, subject to budgetary constraints, from September 1, 1979. The initial appointment is for a period of two years, renewable. Salary will depend on experience; the base salary for the Assistant Professor rank currently is $18,604 per annum.

Applications, including an up-to-date curriculum vitae, reprints of published research, and the names of three referees should be sent to: Dr M. Mackauer, Chairman, Department of Biological Sciences, Simon Fraser University, Burnaby, B.C., Canada, V5A 1S6. Deadline for receipt of applications is January 31, 1979 or when position filled. 8390(A)

UNIVERSITY OF READING

LECTURESHIP IN FOOD QUALITY CONTROL

Applications are invited for a Lecturership in food quality control tenable at the National College of Food Technology, Weybridge, which is part of the University. Candidates should hold appropriate qualifications and have knowledge and experience of quality control systems and/or techniques of food analysis. The successful candidate will be expected to develop an experimental research programme in a relevant field of study, and contribute to the teaching at undergraduate and postgraduate levels.

The person appointed should take up duties as soon as possible.

Further information may be obtained from the Registrar (Room 214, Whiteknights House), The University, Whiteknights, Reading RG6 2AH, by whom applications should be received not later than December 16, 1978.

8443(A)

PROFESSOR OF MOLECULAR BIOLOGY

The Department of Molecular Biology of Vanderbilt University seeks to fill a senior capacity position at the level of Professor or Associate Professor. Candidates should have a noteworthy research programme in the chemical or physical aspects of molecular biology. Ample laboratory space and financial support to facilities relocation of the research programme are available. The teaching responsibilities are modest, permitting emphasis on research and research training. Salary negotiable. Informal inquiries are welcome. Alternatively, please send curriculum vitae, biblography, a description of research and teaching interests, and names of three references to: Dr Oscar Touster, Department of Molecular Biology (Box 1820, Station B.), Vanderbilt University, Nashville, Tennesse 37235. An Affirmative Action/Equal Opportunity Employer. 8393(A)

CHELSEA COLLEGE

University of London

TECHNICIAN 2B

required for small but active Human Biology Department in the Basic Medical Sciences Group. Duties will include assistance in both teaching and research areas, tissue culture experience an advantage. Salary within the range £2,993 to £3,345 per annum inclusive of London Allowance.

Application forms from Personnel Office, Chelsea College, University of London, Friese Greene House, Chelsea Manor Street, London SW3, to be returned by November 30, 1978.

8489(A)

Organic Chemist

Pesticide Research

The Plant Protection Division of ICI wishes to recruit two PhD Organic Chemists to lead small teams concerned with the discovery of novel compounds with pesticidal or plant growth regulating activity. We seek imaginative scientists of proven research ability, able to conceive and carry out new ideas for the design of biologically active molecules. The interests of the successful candidates will extend beyond the bounds of organic chemistry to include an appreciation of structure-activity relationships, biochemistry and biology. The job demands the ability to work constructively as a member of a multi-disciplinary project team.

The position will appeal to candidates who have experience in the field of pesticide or medicinal chemistry, either in industry or in a university post doctoral position.

Jealott's Hill is the centre for pesticide research and development work carried out by the Plant Protection Division of ICI. The Research Station is situated in pleasant rural surroundings between Bracknell and Maidenhead in Berkshire.

We offer competitive salaries and the Company has a Profit-Sharing Scheme and Contributory Pension Scheme. Assistance with removal expenses and house purchase may also be available.

If you wish to apply please write or telephone for an application form to:

Mr. D. Spence, Personnel Officer, ICI Plant Protection
Division, Jealott's Hill Research Station,
BRACKNELL, Berkshire RG12 6EY
BRACKNELL 24701 Ext 3350

ICI

Plant Protection Division

8457(A)

PROFESSOR OF NATURAL SCIENCES

The Institute for Advanced Study invites applications and nominations for the post of professor of natural sciences. This is a tenured position. Candidates should have distinguished records of achievement in research and must demonstrate the capability of further significant research contributions. The ability to stimulate and assist visiting postdoctoral members is an important qualification for the position. Theoretical research is preferred; no laboratory facilities are available. Professors are required to be in residence two terms each year. Women and members of minority groups are encouraged to apply.

Please address all inquiries and applications to Dr Harry Woolf, Director, The Institute for Advanced Study, Princeton, New Jersey 08540. Applications should include a vita and a list of publications. 8461(A)

KING'S HEALTH DISTRICT (TEACHING)

TRAINEE TECHNICIAN

to work in the Pharmacy Quality Control Laboratory to assist with the analysis of medicinal products, using advanced instrumentation. Applicants should possess one or two 'A' levels or five 'O' levels (including Chemistry). Possibility of day release to study for H.N.C. or O.N.C. SCIENCE GRADUATES WILL BE CONSIDERED.

Starting salary, according to age and qualifications, within range: £2,256 (at age 16) to £3,264 p.a. inclusive.

Further information from Miss Hodges on ext. 2472. Application form and job description available from the District Personnel Department, King's College Hospital, Denmark Hill, London SE5 9RS. Tel: 01-274 6222 ext. 2254.

Closing date: December 1, 1978.

8442(A)

UNIVERSITY OF SINGAPORE

CHEMICAL ENGINEERING

PROFESSORSHIP

Applications are invited for appointment as Professor in the Department of Chemical Engineering. The successful candidate should have considerable teaching, industrial and administrative experience. Gross monthly emoluments in the range from S$3,745 to S$5,775 approx., the initial amount depending on the candidate's qualifications and experience In addition, the University pays a 13th month annual allowance of one month's salary in December of each year. Leave, subsidised housing, medical and provident fund benefits are available. Candidates should write to: *The Registrar, University of Singapore, Kent Ridge, Singapore 5,* giving curriculum vitae (bio-data), with full personal particulars and also the names and addresses of three referees. 8395(A)

BHP

DIRECTOR

MELBOURNE RESEARCH LABORATORIES

AUSTRALIA

The Broken Hill Proprietary Co. Limited (BHP) is the largest Company in Australia, with annual sales of $A2,374 million and employing some 59,000 people in a variety of activities covering steel, minerals, oil and gas and manufacturing. These activities, which range through exploration, mining, extraction, transportation and fabrication, are supported by extensive research and development programmes.

Following the promotion of Dr. W. J. McG. Tegart to an executive position at Head Office, a new Director is being sought for BHP Melbourne Research Laboratories which are one of two corporate laboratories for the BHP Group. The Director will be responsible for the total research programme in materials research and development, metal forming, mill technology, welding, product development, transportation, energy, and engineering. While the major effort is directed to the BHP Group, substantial contract work is being carried out for external companies and for Government bodies.

The Laboratories are situated on 10 hectares at Clayton, a suburb of Melbourne and were opened in 1968. They currently employ 140 people, of whom 65 are professionals. The Laboratories are well equipped by world standards and are essentially self-contained with respect to services. Their annual budget is of the order of $A3.5 million.

Applicants should have research experience and a proven record in management. Salary will be in the range $A30,000-40,000 p.a. depending upon experience and qualifications, and a Company car is provided. The Company operates a generous superannuation scheme and reasonable relocation and removal expenses will be paid. Subsidized accommodation will be provided for up to six months on arrival in Australia.

Applications containing full personal particulars, including age, qualifications, experience, publications, telephone number and name of referees should be marked "Confidential" and addressed to:

Dr. R. G. Ward,
General Manager Research and
New Technology,
The Broken Hill Proprietary Co. Ltd.,
Melbourne. Victoria. Australia. 3001

Applications should reach the above address by 15th January, 1979

BHP 454/OS

8386(A)

Anglian Water Authority

ASSISTANT TEAM LEADER

(Mathematics)

Post Ref: H6R003 Grade 6

£5,133–£5,493 p.a.

Applications are invited for the above post currently based at the Great Ouse River Divisional offices, Cambridge. The successful applicant should preferably be a graduate in mathematics with experience in the water quality modelling of estuaries, coastal waters and reservoirs, and the organisation and collection of associated data. In addition to his individual projects, the successful applicant will also be expected to assist other team members in all aspects of their varied chemical and biological investigations, including computer programming, data processing and statistics.
The post carries a Regular User Car Allowance and N.J.C. conditions of service, including a contributary pension scheme, apply.
Please wrote, or telephone 0223 61561 ext. 259 for an application form (returnable by Monday 11th December, 1978) to Mr. M. J. Pearson, Regional Research Team Leader:—

GREAT OUSE RIVER DIVISION,
Great Ouse House, Clarendon Road,
Cambridge, CB2 2BL 8486(A)

THE UNIVERSITY OF HULL SENIOR LECTURER/ LECTURER IN APPLIED PHYSICS

Applications are invited for the post of Senior Lecturer/Lecturer in the Department of Applied Physics for work on satellite laser ranging, tenable from a date to be arranged.

Salary scale: £3,883 to £7,754 per annum (under review) plus superannuation benefits.

Applications (6 copies) giving details of age, qualifications and experience, together with the names of three referees, should be sent by December 4, 1978 to the Registrar, The University of Hull, Hull HU6 7RX from whom further particulars may be obtained. 8453(A)

NORTHWESTERN UNIVERSITY

DEPARTMENT OF GEOLOGICAL SCIENCES

A new, regular assistant professorship is available September, 1979. Al applicants with strong quantitativ backgrounds in the geological science should forward, as soon as possible their curriculum vitae, list of publications, and a statement of researc interests and goals to:

E. H. Timothy Whitten, Chairman
Department of Geological Sciences
Northwestern University,
Evanston, Illinois 60201, U.S.A.

Northwestern University is a equal-opportunity / affirmative-actio employer. 8417(A)

Ministry of Agriculture, Fisheries and Food, Pest Infestation Control Laboratory, Slough

Acarologist

■ **Join small team ■ Study the biology and systematics of storage mites ■ Examine the relationship between population increases and environmental conditions ■ Investigate effect of nutrition and feeding habits of mites on the development of infestation in stored cereals.**

☐ 1st/2nd hons degree or equivalent in an appropriate biological subject ☐ At least 2 years experience in acarology required ☐ Appointment as Higher Scientific Officer (£4375–£5725) ☐ Ref: SB/39/AF.

■ Application forms (for return by 7 December 1978) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke (0256) 68551 (answering service if office closed).

PLANT BREEDING INSTITUTE

APPOINTMENT

OF

DIRECTOR

Applications are invited for the post of Director of the Plant Breeding Institute, Cambridge, which was recently vacated by the Director, Dr R. Riley FRS, on his appointment as Secretary to the Agricultural Research Council in October 1978. The Institute, which is grant-aided by the Agricultural Research Council, has its own Governing Body and is engaged in research in plant breeding and relevant sciences directed towards the improvement of agricultural crops. Approved varieties bred at the Institute are marketed through the National Seed Development Organisation.

Applicants should have high scientific qualifications and research experience relevant to the Institute's work. The post is graded Chief Scientific Officer. Salary is £13,047 per annum and it is the Government's intention that the salary for this grade will be £13,908 per annum from April 1979 and £14,770 per annum from April 1980.

Applications, including the names of three referees, should be received by 31 January 1979 and should be addressed to the Secretary, Plant Breeding Institute, Maris Lane, Trumpington, Cambridge CB2 2LQ, from whom further particulars may be obtained.

8447(A)

LECTURER/ASST. PROFESSOR AT THE UNIVERSITY OF TROMSOE, NORWAY

Applications are invited for a position as lecturer/asst. professor in cytology/plant physiology at the Institute of Biology and Geology. University of Tromsoe in Tromsoe, Norway. The succsessful candidate is expected to teach undergraduate and graduate courses to students in biological sciences. Teaching responsibilities also include a graduate techniques course in electron microscopy and cytology. Instruction can initially be done in English, if necessary.

The position also provides an opportunity to conduct cytological/cytochemical research. Persons with research interests in disease resistance of plants and the biochemical basis for pathogenicity in microorganisms are especially encouraged to apply. The University of Tromsoe is unique in being the most northerly situated university of the world. Its Institute of Biology and Geology has completely new facilities for conducting research including fully equipped laboratories for physiological and biochemical analyses, growth chambers and a phythotron. Computer terminals and exellent library services are also available. The electron microscope laboratory is fully equipped for all types of scanning and transmission electron microspopy.

The position is available immediately. Salary from 91439 Nkr. to 114392 Nkr. depending on qualifications.

Application deadline: Des. 20th. 1978.

For further information contact: **Sylvia Labugt, Institute of Biology and Geology, University of Tromsoe, P. O. Box 790, N-9001 TROMSOE, tph.no. (083) 70011.**

8413(A)

Ministry of Agriculture, Fisheries and Food, Plant Pathology Laboratory, Harpenden

Agriculturist/ Horticulturist/ Biologist

■ Make field surveys and visit farmers to determine the extent and methods of use of pesticides ■ Process data by computer.
□ Degree, HNC or equivalent in agricultural, horticultural or biological subject □ Experience in computing advantageous □ Possession of current driving licence essential □ Age normally under 27 □ Appointment as Scientific Officer (£2840–£4410) □ Ref: SB/18/AG.

■ Application forms (to be returned by 13 November 1978) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke (0256) 68551 (answering service if office closed).

Safety in the Food & Cosmetic Industries

Information Scientist

. . . to work on problems associated with the safety in use of cosmetics, food-contact materials and medical devices. The work includes scanning literature for relevant articles for reference files, carrying out literature surveys on various chemicals associated with cosmetics and food-contact materials, preparing reports and papers for consideration by expert advisory committees, collating and evaluating data, and consulting with representatives of the cosmetic and food industries.

Candidates, normally aged under 30, should have a degree or equivalent qualification in a relevant discipline and several years postgraduate experience. A knowledge of toxicology would be an advantage.

Appointment as Higher Scientific Officer (£4560–£5910). Starting salary according to qualifications and experience. Non-contributory pension scheme. Promotion prospects.

For further details and an application form (to be returned by 9 November 1978) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote ref: SB/3/KE.*

SENIOR FACULTY POSITION DEPARTMENT OF ASTRONOMY AND STEWARD OBSERVATORY, UNIVERSITY OF ARIZONA

The University of Arizona expects to make a senior faculty appointment (Associate or Full Professor) in the Department of Astronomy and Steward Observatory. The department has an interest in increasing its involvement in theoretical astrophysics and in space related, optical and infrared research. Applicants with distinguished research records in any areas of astronomy and astrophysics will, however, be considered seriously. Research facilities available include the 4.5 meter Multi-Mirror Telescope, 2.3 and 1.5 meter telescopes, and the University's CDC Cyber 175 and Dec 10 computers. Interested scientists are requested to send a vitae and biblography by February 15, 1979 to either Dr Rodger I. Thompson, Chairman: Search Committee, or Dr Peter A. Strittmatter, Director, Steward Observatory, University of Arizona, Tucson, AZ 85721. The University of Arizona is an Equal Opportunity/Affirmative Action Title IX/Section 504 Employer.

8420(A)

Experienced Toxicologists

We are looking for two established toxicologists to join our Toxicology and Drug Safety Unit

They will work in our Animal Studies Section and be expected to take an active role in the design, conduct and evaluation of experiments forming part of the safety assessment of a wide range of potential human and veterinary medicines The abilities to guide the work of less experienced staff and to communicate information are essential. Applicants of either sex are likely to have a good Honours degree, but in any event must possess at least three years' directly relevant experience. For one of these openings, some expertise in the area of Reproductive Toxicology would be an advantage but is not essential.

Remuneration will reflect the experience and qualifications of the successful applicants and re-location expenses will be paid in approved circumstances

If you wish to apply, please write to:-
John Atkinson, Site Personnel Manager,
Beecham Pharmaceuticals – Research Division, Medicinal Research Centre,
The Pinnacles, Harlow, Essex CM19 5AD

or telephone our answering service on Harlow (0279) 419373 for an application form, quoting our reference 54/N

Beecham Pharmaceuticals

8435(A)

CNS Pharmacologist

Roussel Laboratories Limited is part of an international group engaged in research, development, manufacture and marketing of a wide range of pharmaceutical and allied products.

We wish to recruit a graduate pharmacologist to fill a key role in a project team investigating and developing novel compounds with activity on the central nervous system Ideally, we are looking for one or two years' post-graduate experience in this area although we will consider candidates who have recently obtained a relevant degree or equivalent qualification

The Research Division is based at our modern manufacturing laboratories near Swindon Conditions of service are excellent, including generous assistance with relocation to this attractive part of Wiltshire

Please write or telephone for an application form to.
Rosemary Curtis, Roussel Laboratories Limited, Kingfisher Drive, Covingham, Swindon, Wilts SN3 5BZ
Tel. Swindon (0793) 24411.

ROUSSEL

8436(A)

UNIVERSITY OF SOKOTO— NIGERIA

Applications are invited for the following posts in the DEPARTMENT OF GEOGRAPHY:

PROFESSOR

Must have considerable teaching experience at university level plus administration and research experience Should have academic interest in Africa or the tropical world. Will be expected to organise, develop teaching and research in the Department and provide leadership.

SENIOR LECTURER/ LECTURER

Preference will be given to candidates who have specialised in Physical Geography and are qualified to teach Geomorphology or climatology. Must have Ph D and between 3 to 5 years of teaching and research at University level.

Salary scales Professor, N11,268 to N12,420 per annum (£8,942 to £9,857 p.a.), Senior Lecturer, N7,764 to N8,724 p a (£6,161 to £6,923 p a sterling); Lecturer N5,460 to N6,984 p.a (£4,333 to £5,542 p a sterling) (£1 sterling=N1 26.) There may be salary supplementation for Professors and Senior Lecturers in range £2,160 to £2,916 p a. (sterling) for married appointees or £NIL to £750 p a (sterling) for single appointees (reviewed annually and normally free of all tax) plus provision of children's education allowances and holiday visit passages. There will not be salary supplementation and associated benefits for appointees to Lecturer level Family passages, car allowance, housing allowance/partly furnished accommodation Fringe benefits include pension scheme or contract addition of salary (partly taxable)

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent to Registrar, University of Sokoto, PMB 2346, Sokoto, Nigeria, by December 19, 1978.

Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 8493(A)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF EARTH SCIENCES

Applications are invited for the post of RESEARCH ASSISTANT or RESEARCH FELLOW for research in CHEMICAL OCEANOGRAPHY The successful candidate will work on a NERC funded programme concerned with the geochemical cycling of lanthanides and transition metals in marine sediments. The work is part of a collaborative project on oceanic processes involving the University of Leeds, the Open University, the University of Southampton and the Institute of Oceanographic Sciences, Wormley. It involves sample collection aboard RRS Discovery, and analyses using radioisotope-dilution and isotope-dilution techniques. Applicants should be graduates with experience in chemical techniques and must be willing to take part in research cruises involving absences abroad, and in visits to other research laboratories. For appointment at the Research Fellow level a Ph D. degree is required. The appointment will be for a fixed period of three years.

Salary at an appropriate point on either the IB Scale (£3,384 to £4,882) or the IA Scale (£3,883 to £6,555) for Research and Analogous Staff Both salary scales are currently under review.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 49/9/D. Closing date for applications December 10, 1978.

8479(A)

QUEEN ELIZABETH COLLEGE
Kensington
(University of London)
POSTGRADUATE RESEARCH ASSISTANT
Human Gene Localisation

Applications are invited from graduates in Biochemistry, Molecular Biology or related subjects to assist in a project, supported by the Medical Research Council, on in situ hybridisation for human gene localisation. The appointment will be for 2 years, 9 months, in the Department of Biochemistry. Salary up to £4,408 p.a. (Range 1A) plus London allowance of £450 p.a.

Applications to Professor D Robinson, Biochemistry Department, Queen Elizabeth College, Campden Hill Road, London W8 7AH

8473(A)

CELL BIOLOGIST

The Department of Biology at the University of California at Riverside has a faculty position at the level of Assistant Professor available September 1, 1979 Primary teaching responsibilities will be in the area of cell biology both at the undergraduate and graduate levels. Candidates must have postdoctoral experience and show evidence of ability to initiate and sustain a productive high quality research program. The department is especially interested in candidates with research experience in biochemical, genetic and/or electron microscopical approaches to the study of cell ultrastructure, morphogenesis, cell surfaces, and cell interactions

Applicants should provide a curriculum vitae, reprints and a brief description of research and teaching interests Additionally, at least three letters of support should be sent. The University of California is an equal opportunity and affirmative action employer Applications are invited from all qualified individuals, especially women and members of minority groups.

Send applications to W L Belser, Chairman of the Search Committee, Department of Biology, University of California, Riverside, Calif. 92521

Ayrshire and Arran
Health Board
North Ayrshire and
Arran District

BALLOCHMYLE HOSPITAL
SENIOR CYTOGENETICIST

Senior Cytogeneticist (Science Graduate) required for Ayrshire Area Laboratory to work in a developing diagnostic service for the detection of human chromosome aberrations.

Appropriate qualifications and experience in cytogenetics and cell culture are essential. The post will initially be based at Ballochmyle Hospital but will move to the new North Ayrshire District General Hospital in 1979.

Further details may be obtained from the Pathology Department, Ballochmyle Hospital (Catrine 281, ext. 23).

Applications with full details of qualifications and experience and names of two referees, to the North Ayrshire District Medical Officer, 1 Hill Street, Kilmarnock. 8425(A)

The Division of Clinical Nutrition,

THE HOSPITAL FOR SICK CHILDREN

Toronto, Ontario

is seeking applicants for a position as Research Associate (full time staff member). The applicant should have received his/her doctorate in Nutritional Biochemistry or Animal Nutrition, and shoult have had one or two years postdoctoral experience. The applicant will be expected to conduct independent research in Nutrition; both in human and in animal models. The position will also entail participating in the teaching load of the Division. Applicants are requested to correspond with Dr P. B. Pencharz, Head, Division of Clinical Nutrition, The Hospital for Sick Children, 555 University Avenue, Toronto, Ontario M5G 1X8. 8410(A)

POSITIONS AVAILABLE THREE FACULTY POSITIONS

Two Associate or Full Professors in Organic Chemistry or related chemical research area. One tenure track Assistant Professor in Analytical Chemistry. Applicants for the tenured Associate or Full Professorships should have an established research program of high quality and be experieinced teachers at the undergraduate and graduate level. Applicants for all positions must be committed to excellence in research and teaching. A complete curriculum vitae, which includes a documented summary of past accomplishments and future research plans, should be submitted to Dr Gordon Harris, Chairman of the Search Committee, Chemistry Department, State University of New York at Buffalo, Acheson Hall, Buffalo, New York 14214. Qualified female and minority applicants are encouraged to apply. Deadline for applications is January 31, 1979.

THE STATE UNIVERSITY OF NEW YORK AT BUFFALO IS AN EQUAL OPPORTUNITY/AFFIRMATIVE ACTION EMPLOYER.

8414(A)

RICHARD DIMBLEBY
DEPARTMENT OF CANCER RESEARCH
ST THOMAS'S HOSPITAL MEDICAL SCHOOL
RESEARCH TECHNICIAN

required for post vacant from January , 1979. Particular duties concern the culture of mammalian cells derived rom human and animal tissues and esearch into the response of such cells o radiotherapy and cancer chemoherapeutic drugs. Previous experience n a cell culture laboratory is desirable but applicants with general laboratory raining can be considered. Qualificaions should include M.I.S.T. or O.N.C. or equivalent. Please write giving telephone No., curriculum vitae and name and address of two referees o Professor A. H. W. Nias, St. Thomas's Hospital Medical School, London SE1 7EH. 8477(A)

QUEENSLAND INSTITUTE OF TECHNOLOGY

BRISBANE — AUSTRALIA

SENIOR LECTURER IN PHYSIOLOGY

Applications are invited from medical or science graduates holding suitable higher qualifications. The appointee will be expected to exercise leadership in teaching physiology and functional anatomy at the undergraduate and graduate level and to develop the research and investigative activities of the physiology area of the Department of Medical Technology.

Salaries: Senior Lecturer 1 $A22,289 to $A23,737; 11 $A20,365 to $A21,810. Appointment will be made in accordance with qualifications and experience.

Q.I.T. is a multi-disciplinary institution with an enrolment of approximately 7,000 students. Brisbane, the State capital of Queensland, has a population of around one million, and enjoys a climate similar to that of southern Spain.

Further information may be obtained from the Personnel Officer, Q.I.T., G.P.O. Bor 2434, Brisbane Q. 4001.

Applications quoting reference No. V.132/78, full details, telephone number together with a recent photograph should reach the Personnel Officer by December 16, 1978.

8448(A)

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(University of Reading)

CHEMISTRY DEPARTMENT

Applications are invited for a scientist to participate in research into the functional properties of milk protein. The work will involve separations, identification and quantification of proteins, the enzymic and chemical modification of proteins and examination of their functional properties. Honours degree or equivalent in chemistry, biochemistry or food science is required. Some experience in protein chemistry would be advantageous.

Appointment will be as Scientific Officer (£2,839 to £4,415) with starting salary according to qualifications and experience. Non-contributory superannuation.

Application forms and further details are obtainable from the Secretary, N.I.R.D., Shinfield, Reading RG2 9AT. Quote reference 78/35. 8444(A)

The Division of Clinical Nutrition

THE HOSPITAL FOR SICK CHILDREN

Toronto, Ontario

is seeking applicants for, a position as a geographical full time staff member. The applicant should be a trained Paediatric Physician or Surgeon, with a demonstrated interest and competence in Nutrition Research. The position will entail, patient care, teaching and the conduct of original research, in the area of Human Nutrition. Applicants are requested to correspond with Dr P. B. Pencharz, Head, Division of Clinical Nutrition, The Hospital for Sick Children, 555 University Avenue, Toronto, Ontario M5G 1X8. 8389(A)

UNIVERSITY OF EDINBURGH
RESEARCH TECHNICIAN

required to work in the
DEPARTMENT OF MOLECULAR BIOLOGY

on a project entitled 'Bacterial plasmids and conjugation' An Honours degree, or equivalent, in an appropriate subject is required. Salary on the scale £3,186 to £3,770 p.a. (under review). Appointment to take effect from January 1, 1979 for a period of five years. Ref. NO38.

Application forms for the above post can be obtained from the Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS. Telephone: 031-556 2930. 8434(A)

Food Chemist in Government Research (SSO/HSO/SO) £2839-£6898

Applications are invited from suitably qualified candidates for a pensionable post in the Agricultural and Food Chemistry Division of the Department of Agriculture situated at Newforge Lane, Belfast.

The duties will include research and advisory work in Food Chemistry snd the successful candidate may also be required to undertake lecturing duties in Food Chemistry and Allied subjects of the Honours course leading to the degree of BSc in Food Science at the Queen's University of Belfast.

Appointment may be at Senior Scientific Officer, Higher Scientific Officer, or Scientific Officer level.

SENIOR SCIENTIFIC OFFICER

Over 25 and under 32 years of age on December 31, 1978, and possess a 1st or 2nd class Honours Degree in Food Science, Chemistry, Biochemistry or Agricultural Chemistry and at least 4 years' appropriate post-graduate experience.

HIGHER SCIENTIFIC OFFICER

Under 30 years of age on December 31, 1978, and possess an Honours degree as above and at least 2 years' appropriate post-graduate experience.

SCIENTIFIC OFFICER

Under 27 years of age on December 31, 1978, with an Honours degree as above.

Preference may be given to candidates with appropriate research experience in Food Chemistry or experience in teaching Food Chemistry and the Chemistry and Physics of Food Processing.

Exceptionally applications may be considered from candidates over the age limits who have specialised experience.

The Commissioners may decide to interview only those applicants who appear from the information available (including level of academic attainments and experience) to be best qualified.

SALARY SCALES

Senior Scientific Officer ..	£5,154 to £6,898
Higher Scientific Officer ..	£4,101 to £5,448
Scientific Officer	£2,839 to £4,415

Grading and starting salary will be related to qualifications and experience.

Please write or telephone for an application form quoting job reference SB 406/78/N to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 256). Completed forms must be returned to arrive not later than November 30, 1978.

UNIVERSITY COLLEGE CORK

The Governing Body invites applications for the following office:

PROFESSORSHIP OF GEOLOGY

Salary range (from March 1, 1979) is: £9,775 to £11,305 p.a.

Application forms and further details may be obtained from the undersigned.

Latest date for receipt of applications is **Wednesday, December 6, 1978.** M. F. Kelleher, Secretary. 8462(A)

Laboratory Technicians

Hoechst UK Limited are looking for people to take up these challenging positions on their site at Walton, Milton Keynes.

There are currently two vacancies in the **Pharmaceutical Development Department.**

Analytical Section

The job consists of taking and analysing samples generated during the development of new pharmaceutical dosage forms. Raw materials, drug substances, pharmaceutical excipients, process investigation samples and finished products are tested using a variety of physical and chemical methods.

Formulation Section

The person appointed will assist in the development of pharmaceutical dose forms – tablets, capsules and liquid products – and prepare small scale batches of products for evaluation.

Candidates, male or female, for both these posts should have laboratory experience and be educated at least to 'A' level in Chemistry.

Hoechst UK is a part of one of Europe's leading companies and the salaries and conditions of employment are of the standard to be expected from such a company.

Please write or phone for an application form to:

The Personnel Department, Hoechst UK Limited, Walton Manor, Walton, Milton Keynes, Bucks. Tel: Pineham 5068.

UNIVERSITY OF EDINBURGH
DEPARTMENT OF GEOPHYSICS
POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the post of Postdoctoral Research Fellow to work on the analysis of regional gravity data in Britain. The project is collaborative with the Applied Geophysics Unit of the Institute of Geological Sciences and other University groups, and has the objective of preparing and interpreting a regional gravity map of Britain stripped of the contribution of upper crustal sources.

Applicants, who will need to be numerate with computing experience, should have a good background knowledge of British geology. Although based in Edinburgh, they should be prepared to spend part of their time working in collaborating institutions.

The appointment is for three years with a salary of £4,382 to £4,882 p.a. and immediate availability. Requests for further information and applications, including a full curriculum vitae and two referees, should be made to: Dr R. G. Hipkin, Department of Geophysics, J.C.M.B., Mayfield Road, Edinburgh EH9 3JZ. Please quote Reference 5064.

THAMES POLYTECHNIC
SCHOOL OF MATERIALS SCIENCE AND PHYSICS
X-RAY and NUCLEAR LABORATORY TECHNICIAN GRADE 5

Applications are invited for a Technician for the X-ray and nuclear laboratories who will be required to operate X-ray equipment, handle radioactive sources and be responsible for keeping exposure records. Candidates should have a recognised apprenticeship or HND/HNC qualification and at least eight years' relevant experience.

Salary scale: £3,474 to £4,011 inclusive.

Further particulars and form of application may be obtained from the Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6PF, to whom completed applications should be returned by November 28, 1978. 8496(A)

CENTRAL PUBLIC HEALTH LABORATORY
National Collection of Type Cultures
SYSTEMS DESIGNER/ PROGRAMMER

A science graduate is required for the computer operation of a bacterial identification service. Bacteria from clinical sources are identified by probabilistic analysis of test results by reference to computer-stored data bases. Systems use Optical Mark Reader forms, Data Recognition (Dataterm 3) Machine, Extel punch tape terminal connected to the LUCS CDS 6500 time sharing system; current software in FORTRAN IV. There is considerable scope for improving the responsiveness of the system and the efficient storage and retrieval of data, and to revise the methodology or explore alternative methods.

Candidates with five years postgraduate experience may be appointed to the Senior Scientist Grade.

Salary on probationary scale £2,991 to £4,275 plus London Weighting, Post Probationary scale £3,798 to £4,899 plus London Weighting or Senior Scientific scale, if applicable, £5,451 to £6,837 plus London Weighting.

Ring 01-205 7041 for a more detailed job description (Dr L. R. Hill, on extn. 47) and for conditions of employment and application form (Personnel Officer, on extn. 46). 8470(A)

ROTHAMSTED EXPERIMENTAL STATION
Harpenden, Herts. AL5 2JQ
SCIENTIFIC OFFICER

to work in the Entomology Department insect survey. The work will consist of sorting and identifying aphids, curating and compiling records, with opportunity for ecological studies. Some knowledge and experience of aphid taxonomy is desirable.

Qualifications: Honours Degree or equivalent in Zoology, Agricultural Entomology or Applied Entomology, or Pass Degree, H.N.C., or equivalent with relevant post qualifying experience.

Appointment in grade of Scientific Officer (£2,839 to £4,415 per annum). Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees, and quoting Ref. 370 by December 8, 1978. Further details on request. 8428(A)

ICI

Research Biochemist

ICI's Corporate Laboratory has a vacancy for a research biochemist, with experience of preparative and analytical enzymology, and some knowledge of oxidation and reduction in biological systems and lipid biochemistry.

The successful applicant will become a member of an interdisciplinary team studying the industrial applications of enzymes and membranes and will need to be able to interact effectively with people of all levels, both within and outside ICI. It is hoped that he she will develop his/her own line of research within the general remit of the team.

A good honours degree or equivalent in biochemistry, coupled with relevant postgraduate experience are desirable qualifications for the post.

Please write, enclosing full curriculum vitae to:

Mrs C. Cleave
Personnel Assistant
ICI Corporate Laboratory
PO Box No 11
The Heath
RUNCORN Cheshire WA7 4QE

Culham
Laboratory

require a

PHYSICS GRADUATE

to work in the general field of particle throughput and radiation energy loss in magnetically confined plasma devices.

Current work involves critical assessments of the needs for atomic data coupled with measurements of cross-sections using colliding beam techniques.

Post graduate experience preferably in a related area of experimental physics is required.

Salary: £4,388-£7,380 (according to age, qualifications and experience).

For an application form write to (or telephone):

Mrs Diana Townsend
Personnel Department
UKAEA
Culham Laboratory
Abingdon
Oxon OX14 3DB
Telephone No.: 0235 21840 ext. 250

8421(A)

Liquid Chromatography . . .
. . . science with a sales bias

Du Pont (U.K.) Ltd., one of the world's largest chemical companies, are expanding their share of the liquid chromatography market.

This new appointment, in their Instrument Product Division at Hitchin, is the link beween Du Pont's introduction of new instrumentation and columns and the continuously expanding market for this sophisticated technology.

You will arrange and develop customer demonstrations, lectures and seminars, in the UK and occasionally abroad, in support of your own sales programme for new and existing customers and ensure effective after-sales service through field engineers.

Ideally, you will be around 30 with graduate or postgraduate qualifications in chemistry, or related fields, and some experience in the selling and marketing of HPLC would be an advantage.

However, we would also invite applications from recent graduates or postgraduates in the above fields who in their first jobs have demonstrated the personality, determination and drive to develop into a successful sales role.

This represents a real opportunity to develop in both professional and personal terms within an acknowledged market leader. The rewards are an above-average salary, regularly reviewed, prestige company car, pension plan and relocation package.

Please telephone (01-629 1844 at any time) or write for information and an application form, quoting ref. V.382. **ASL Recruitment Advertising, 17 Stratton Street, London W1X 6DB.**

DU PONT **Instrument Products**

8475(A)

Experimental Officer – Microbiologist

There is a vacancy for a microbiologist in a small team involved in the discovery of new fungicides and bacteria for agriculture. The job-holder will provide cultures of plant pathogens for use in glasshouse and field experiments, and will also conduct mode-of-action studies on fungicides at the morphological/physiological level. This job will suit a person with academic training to first degree or HNC level. Research experience in some aspect of microbiology is essential.

Jealott's Hill Research Station is situated on a pleasant farm estate between Bracknell and Maidenhead.

We offer good salaries and fringe benefits include membership of the ICI Profit Sharing Scheme and Pension Fund. A staff restaurant and recreation club are on site. Subsidised coaches run to and from Jealott's Hill, Bracknell and Maidenhead.

If you are interested in this vacancy, please write for an application form to:

Mr S R Stephenson
Personnel Officer
ICI Plant Protection Division
Jealott's Hill Research Station
Bracknell
Berkshire

Please quite reference number 78/EO Micro Bio.

ICI Plant Protection Division

8438(A)

WOLFSON UNIT OF
Plant Cell Biotechnology
University of Sheffield

The Wolfson Foundation has provided funds to establish a Unit of Plant Cell Biotechnology, based on the Departments of Biochemistry (Dr. M. W. Fowler) and Chemical Engineering (Professor J. A. Barnard), to develop the large-scale culture of plant cells as sources of pharmaceuticals and related chemicals. In addition to its own experimental programme, the unit will maintain close and continuing links with industry.

Vacancies exist for **TWO RESEARCH ASSISTANTS,** men or women, preferably at the post-doctoral level.

One will be concerned with the growth of plant cells in large-scale liquid culture. A knowledge of secondary product metabolism and experience of sterile techniques would be an advantage.

The other will be concerned with biochemical reactor design and scale-up to pilot plant and eventually industrial scale production. Experience of chemical engineering in the pharmaceuticals or related industries would be valuable.

In both cases, staff will be expected to collaborate closely with industry and to foster co-operation between the Unit and outside research organisations.

Salaries on the Research Assistant 1A scales £3,883 — 6,555, according to qualifications and experience. Appointments would be initially for one year with possible renewal.

Those interested should write in the first instance to:

Professor J. A. Barnard,
Department of Chemical Engineering
and Fuel Technology, University of Sheffield,
Mappin Street, Sheffield, S1 3JD
Quoting ref: R212/G 8401(A)

pcb

JUNIOR FACULTY POSITION
DEPARTMENT OF ASTRONOMY AND STEWARD OBSERVATORY, UNIVERSITY OF ARIZONA

The Department of Astronomy and Steward Observatory expects to make an appointment at the Assistant Professor tenure track level beginning the fall semester of 1979. Applicants in any area of astronomy and and astrophysics will be considered; some preference will however be given to applicants with interests in theoretical work or in infrared and optical observations. Facilities available include the 4.5m Multi-Mirror Telescope, 2.3 and 1.5 meter telescopes, and the University's CDC Cyber 175 and Dec 10 computers. Interested applicants are requested to send a vitae and biblography by February 15, 1979 to Dr Rodger I. Thompson, Chairman: Search Committee, Steward Observatory, University of Arizona, Tucson, Arizona 85721. The University of Arizona is an Equal Opportunity/Affirmative Action Title IX/Section 504 Employer.

Fermentation Process Development

Paris

Roussel Uclaf, the major international Group in the chemical and pharmaceutical industries, is seeking a Biochemical Engineer for its Research Centre located near Paris where the bulk of the Group's research work is carried out

As the Section Head, Fermentation Process Development, reporting to the Biochemical Development Manager, you will be responsible for

- new product process development, particularly of new techniques for fermentation processes and product recovery,
- process maintenance and improvements related to the production of existing fermentation products

Ideally, you should have a PhD in a relevant discipline and experience in those aspects of microbiology, biochemistry, chemistry and biochemical engineering necessary for the effective management of a team operating in this field.

Excellent conditions of service include a very competitive salary, contributory pension and free life insurance. Assistance with relocation will be given

Please send full career details to M R de Vitry, Direction du Developpment et de la Gestion des Cadres, Roussel Uclaf, 35 Boulevard des Invalides, Paris 7e, France

JOHN INNES INSTITUTE

DEPARTMENT OF GENETICS

Postdoctoral Fellow required to work on the molecular biology of crown-gall disease induced in plants by *Agrobacterium tumefaciens* Applicants should have, or expect shortly to obtain, a Ph D. in biochemistry, molecular biology or a related field. This post, funded by a grant from the Cancer Research Campaign, is for three years.

Salary will be at an appropriate point on the Higher Scientific Officer scale (£4,101 to £5,448) Non-contributory superannuation

Further particulars may be obtained from the head of the Genetics Department, Professor D. A. Hopwood Applications quoting ref. G/28 with full details of qualifications and experience and the names of two referees, should be sent to the Secretary, John Innes Institute, Colney Lane, Norwich, NR4 7UH

8485(A)

UNIVERSITY OF GLASGOW

LECTURESHIP IN BOTANY

Applications are invited from experimental biologists for a Lectureship in Botany. No field of research interest is excluded but the work of applicants trained in fields other than Botany (e.g. Virology, Molecular Genetics, Environmental Physics, etc.) must be associated with plant tissues after appointment The appointment will begin as soon as possible and no later than October 1, 1979. The initial salary will be £3,883 to £5,604 (interim) on the Lecturers' scale

Further information about the post and department may be obtained from Professor M B Wilkins.

Applications (8 copies), giving the names and addresses of three referees, should be lodged with the Secretary of the University Court, (Room 18), The University of Glasgow G12 8QQ, not later than December 31, 1978

In reply please quote Ref. No. 4111/1M. 8302(A)

FELLOWSHIPS

AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF EARTH SCIENCES

RESEARCH FELLOWSHIPS (3 Posts)

Applications are invited for appointment to the following :

RESEARCH FELLOW IN GEOPHYSICAL FLUID DYNAMICS

Since the appointment of Professor J. S. Turner in 1975, the Geophysical Fluid Dynamics Group has worked in two main research areas: experimental and theoretical studies of mixing and convection processes in the ocean, and theoretical work on the interior of the earth and other planets. Inter-disciplinary research with other groups has also been initiated, in particular a study of the fluid phenomena associated with the formation of ore bodies. The group has a well-equipped laboratory, and has just acquired a DEC Computer for data logging and analysis.

The successful applicant will have considerable freedom to pursue his/her own research within the broad field of fluid geophysics Preference will be given to candidates who have some experience in both theoretical and laboratory modelling, and have demonstrated the ability to relate their results to observational data.

RESEARCH FELLOW IN ISOTOPE GEOLOGY

Candidates for this post should be geologists or geochemists who are trained in the use of isotopes in earth sciences. The successful applicant will join the Isotope Group within the R.S E.S. and conduct research using terrestrial or meteoritic materials in one or more fields of current interest. Present facilities include K-Ar, Rb-Sr and U-Pb age determinations and carbonate C, O isotopic analyses; the use of other isotopic methods is under consideration

RESEARCH FELLOW IN SEISMOLOGY

The School has an active ongoing research program in determining the seismic structure of the mantle under the Australian continent using fixed and mobile arrays. Applicants should be seismologists interested in such studies or in related fields. This would include theoretical seismologists interested in applying synthetic seismogram theory to mantle models or interested in source mechanisms. Applications from geophysicists with broader interests in the structure of the interior of the Earth and terrestrial planets, in investigations of upper mantle lateral heterogeneity, or in tectonic problems in the Australasian region will also be considered for this position. Exceptionally well qualified candidates may be considered for appointment at Senior Research Fellow level.

CLOSING DATE: **JANUARY 31, 1979.**

SALARIES. Salary on appointment will be in accordance with qualifications and experience within the ranges: Senior Research Fellow $A21,201 to $25,289 per annum, Research Fellow $A15,179 to $19,813 per annum Current exchange rates $A=$US1.17:58p.

Appointment as Senior Research Fellow or Research Fellow will be for three years in the first instance with the possibility of extension to five years.

OTHER CONDITIONS: Reasonable appointment expenses are paid Superannuation benefits are available for applicants who are eligible to contribute Assistance with housing is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF 8455(E)

POSTDOCTORAL FELLOWSHIP

(One)

relating to Huntingdon's Chorea in either preclinical sciences, including biochemistry, physiology, pathology or pharmacology, or from such clinical specialities as neurology, psychiatry or human genetics. M D. or Ph.D. required. Initial stipend $13,000 and upward, dependent on degree and previous postdoctoral experience. Deadline is February 1, 1979. To be announced by April 1, 1979. The Fellowship will begin July 1, 1979 and is to be held for one year with renewal for a second year, dependent on progress. Write Huntington Society of Canada, Box 333, Cambridge, Ontario, Canada NIA 5T8 for application and instructions Preference will be given to Canadians, or landed immigrants to Canada 8483(E)

Postdoctoral Fellowship in ENZYMOLOGY

TRENT UNIVERSITY CANADA

Postdoctoral position available early in 1979 for enzymologist to investigate biosynthesis of coumarins. Experience with plant systems desirable but not essential Send curriculum vitae and names of two referees to Dr S. A Brown, Department of Chemistry, Trent University, Peterborough, Ont., Canada K9J 7B8. 8387(E)

POSTDOCTORAL FELLOWSHIP

Two three-year postdoctoral fellowships are available at the Friedrich Miescher-Institut, Basel, in a group working on several aspects of human interferon.

BIOCHEMIST

Preferably experienced in protein purification and/or protein chemistry. The research will involve production and purification of human lymphoblastoid interferon, its characterisation and mode of action. Experience in mammalian tissue culture methods would be of advantage but is not essential.

MOLECULAR BIOLOGIST

Experience in RNA and DNA metabolism is essential. The project will include mRNA isolation, *in vitro*—translation and the cloning of DNA sequences in bacterial plasmids

Reply to Dr H. Weideli, The Friedrich Miescher-Institut, P O Box 273, CH-4002 Basel, Switzerland, sending a brief curriculum vitae and names of three referees. 8487(E)

NEW HALL, CAMBRIDGE

New Hall invites applications for a College Lectureship (with Fellowship) in Physiology from October 1, 1979 Further particulars may be obtained from the President, New Hall, Cambridge CB3 0DF. The closing date for applications is December 16, 1978.

8465(E)

FELLOWSHIPS

UNIVERSITY OF EDINBURGH
Postdoctoral Fellowship on the Molecular Biology of Papilloma Viruses

Applications are invited for a Fellowship for work on a joint project in Edinburgh and Glasgow Universities The project is to investigate the state of bovine papilloma viral DNA in cattle warts and tumours The physiological aspects of the project—including growth of virus and tumours, and transformation of cells—will be conducted at the Veterinary Pathology Department at Glasgow University, directed by Professor W F H Jarrett. The molecular aspects, with which the Fellow will be mainly involved, will be carried out in the Zoology Department at Edinburgh University directed by Drs M. S Campo and U. E Loening The Fellow should be skilled in the current techniques of molecular biology such as hybridisation and restriction enzyme analysis of nucleic acids.

The post is financed by an Agricultural Research Council grant to Professor Jarrett, and the salary is on the Research Range 1A scale The Fellowship can start immediately.

Applications should be sent to Drs M S Campo and U E Loening, Department of Zoology, West Mains Road, Edinburgh 3JT by **January 10, 1979.** Please quote Reference 5068 8458(E)

UNIVERSITY OF EDINBURGH
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for the above post supported by the Medical Research Council and tenable for 2 years from April 1, 1979 The project will investigate the biological significance of cytochrome c methylation and the use of methylation as a means of studying protein . protein interactions Some experience in protein chemistry or enzyme purification is desirable Starting salary in the range £3,883 to £4,631 p a

Further information may be obtained from Dr G W Pettigrew, Veterinary Unit, Department of Biochemistry, Royal (Dick) School of Veterinary studies, Summerhall, Edinburgh EH9 1QH, to whom applications including the names of three referees should be sent before December 31, 1978

In reply please quote Reference 5067 8449(E)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF MICROBIOLOGY
RESEARCH FELLOWSHIP

A postdoctoral research fellow required for studies on the pathogenicity of influenza virus supported by the Medical Research Council Virological training preferred but not essential The post is for a Research Fellow 1A in the range £3,883 to £6,555 (plus superannuation), beginning January 1, 1979 for two years and nine months Maximum starting salary will be £4,882

Applications should be sent to the Assistant Registrar, Science and Engineering, University of Birmingham, P O Box 363, Birmingham B15 2TT by Friday December 8, 1978, and further details can be obtained from Professor H. Smith

Please quote ref. NM4. 8439(E)

POSTDOCTORAL FELLOWSHIPS
DEPARTMENT OF PHYSICS
UNIVERSITY OF WATERLOO
WATERLOO, ONTARIO, CANADA

Applications are invited for postdoctoral research fellowships in physics.

Fellowship stipends range between $11,100 and $12,900 and will depend on the teaching duties. The awards are tenable for the period of one year with a possible renewal for a second year

Research areas include:

Atomic and Molecular Physics, Biophysics, Brillouin Spectroscopy, Crystallography, Electron Microscopy, Electron tunneling, Ellipsometry, Experimental superconductivity, Diffraction Physics, Far-infrared spectroscopy, Infrared and Raman Spectroscopy, De Haas-van Alphen effect, Laser Physics, Lattice dynamics, Magnetoconductivity of metals, Microwave Collision-Induced Absorption and Interferometry, Nuclear magnetic resonance, Semiconductors and amorphous semiconductors, Transport properties of gases and intermolecular potentials, Theoretical studies; magnetic impurities in superconductors, relativistic effects in metals, electronic structure in metals, nonlinear behaviour of elastic dielectrics, lattice dynamics of ionic crystals

The applicants should submit their resumes and the names of three referees to:

Dr C C Lim
Department of Physics
University of Waterloo
Waterloo, Ontario, Canada
N2L 3G1 8391(E)

CALIFORNIA INSTITUTE OF TECHNOLOGY
RESEARCH FELLOWSHIP IN RADIO ASTRONOMY

Caltech's Owens Valley Radio Observatory invites applications for a one-year Research Fellowship in Radio Astronomy This position is associated with the development of a millimeter-wave interferometer, and applicants should have experience in relevant areas such as millimeter-wave spectroscopy, interferometry or instrument design and development and be prepared to devote at least half-time to this work There will also be opportunities for independent research in galactic or extragalactic radio astronomy and for cooperation with other astronomical groups in Pasadena One 10m telescope for millimeter-wave astronomy is now in operation, additional telescopes and low-noise receivers are under construction The appointment is renewable for one or two additional years

Prospective research fellows must complete their Ph D before beginning this appointment Application forms may be obtained from, and should be returned by February 1, 1979, to Professor Alan T Moffet, Director, O V R O Caltech 102-24, Pasadena, CA 91125, U S A

Caltech is an equal opportunity affirmative action employer

8418(E)

POSTDOCTORAL FELLOWSHIP

Available from January 1, 1979 for a Ph D graduate in biochemistry, virology or related area interested in studying the structure and replication of mammalian picornaviruses Applicants must have received the Ph D degree no earlier than April 1, 1978 Salary is $11,600 for the first year

Send curriculum vitae and references to Dr D G Scraba, Department of Biochemistry, University of Alberta, Edmonton, Alberta T6G 2H7 Canada 8388(E)

THE QUEEN'S UNIVERSITY OF BELFAST
RESEARCH FELLOWSHIP
DEPARTMENT OF MICROBIOLOGY AND IMMUNOBIOLOGY

This post involves work on macromolecular aspects of neurological disease Preference will be given to candidates with experience in virology, immunology, particularly in immuno-assay methods and/or nucleic acid hybridisation techniques The Fellowship is tenable for two to three years at a commencing salary of £4,134 per annum with F S S U or U S S

Application forms may be obtained from the Personnel Officer, The Queen's University of Belfast BT7 1NN, Northern Ireland Closing date December 15, 1978 8459(E)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND
GEOPHYSICS AND PLANETARY PHYSICS

Applications are invited for a POSTDOCTORAL FELLOWSHIP or RESEARCH FELLOWSHIP in small, friendly research group with wide interests in theoretical global geodynamics and planetary physics geophysical fluid dynamics, planetary magnetism, rotation, deformation Appointment will be for one year in the first instance, renewable for a second year Send curriculum vitae and names of three referees to Professor M G Rochester, Physics Department, Memorial University of Newfoundland, St John's, Newfoundland, Canada A1B 3X7. 8400(E)

POSTDOCTORAL FELLOW

Laboratory with active program in the study of hormone receptor/antibody interactions has an opening for an individual with experience in hormone receptor separation and purification Although funds for the position at the M R C Canada Postdoctora Fellowship rate of $13,000 are available, the successful candidate would be encouraged and assisted in applications for his/her own Fellowship support Applications should include curriculum vitae and previous research experience The applicant should request three referees to send letters of support to: Dr N R Farid, Faculty of Medicine, Health Sciences Centre, 300 Prince Phillip Drive, St John's, Newfoundland A1B 3V6 8467(E)

UNIVERSITY OF DUNDEE
DEPARTMENT OF MATHEMATICS
RESEARCH FELLOWSHIP

Applications are invited for a Research Fellowship to undertake theoretical investigations in acoustics and electromagnetism Applicants should have appropriate qualifications in Mathematics, Physics or Engineering but need not have worked in the field of acoustics or electromagnetism previously

The starting salary is £3,895 per annum (under review) with U S S. or continuation or F.S S U The appointment will be available from an early date to be agreed for a period of one year in the first instance, with a possibility of subsequent renewal

Applications should be sent by **December 7, 1978** to The Secretary, The University, Dundee DD1 4HN from whom further particulars and further information can be obtained Please quote Reference EST/55/78J. 8416(E)

STUDENTSHIPS

THE ROYAL SOCIETY
John Murray Travelling Studentship in Oceanography and Limnology 1979

Applications are invited for the above Studentship, open to British graduates under the age of 35, for the encouragement of travel and work in oceanography or limnology This award, which may be held for periods from three months to one year, will in 1978 be up to £1,500, adjusted according to qualifications and place and duration of research Applications are especially invited from workers in oceanography and limnology, as well as in zoology, botany, geology, mathematics 8406(F)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF MEDICAL PHYSICS
RESEARCH STUDENTSHIP

Applications are invited for a Research Studentship (£1,990 p a plus approved fees), tenable for 3 years for experimental studies in ultrasonic diagnostic techniques. The student will be expected to register for a higher degree Applicants should preferably have some experience in computer programming

Applications, with curriculum vitae and the names of two referees, to Professor H A B Simons, Department of Medical Physics, Royal Free Hospital, Pond Street, London NW3 2QG. 8385(F)

MICROBIOLOGY graduate required for a Ph D. Studentship in connection with a research project on bacteriological aspects of acne. Apply in writing, with full curriculum vitae and the names of two referees, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref M C.6 8422(F)

ASSISTANTSHIPS

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY
DEPARTMENT OF GEOLOGY
POSTDOCTORAL RESEARCH ASSISTANT
DEEP GEOLOGY PROJECT

Applications are invited for two postdoctoral research assistanships to be taken up as soon as possible. These posts form part of a three year study of the deep geology of Southern England in collaboration with the Institute of Geological Sciences Applicants should be stratigraphers with a broad knowledge of geology and geophysics and an ability to work with experts in other fields A good knowledge of French is an advantage Salary within range £4,359 to £5,579 including London Allowance and USS

Further particulars can be obtained from Dr P Wallace, Department of Geology, Imperial College, London SW7 2BP, to whom applications including curriculum vitae and names of two referees should be sent Closing date December 8, 1978 8491(F)

GRANTS

THE ROYAL SOCIETY
Browne Research Fund
Maurice Hill Research Fund
Marshall and Orr Bequest
GRANTS 1979

The Council of the Royal Society invites applications from qualified research workers for personal grants

(a) from the Browne Research Fund, for research in marine biology at a marine biological laboratory or elsewhere. Preference will be given to those who propose to work on purely scientific problems rather than to those whose work would be primarily directed towards an economic end,

(b) from the Maurice Hill Research Fund (established in memory of the late Dr M. N. Hill, F.R.S., for the encouragement of research in physical oceanography and marine geophysics) for research at sea and/or in the laboratory in physical and chemical oceanography, marine geophysics and geology.

(c) from the Marshall and Orr Bequest for the support of marine biological research

Grants may be used for periods up o one year, and are made on the nderstanding that university or other osts held by applicants will meanwhile be kept open for them ecipients are permitted to use grants hile receiving salaries from regular ppointments.

In 1979 the total amounts available o be shared among all successful pplicants will be about £4,250 from he Browne Research Fund, £8,400 rom the Maurice Hill Research Fund nd £7,820 from the Marshall and Orr equest; individual grants will not rdinarily be more than £750.

Applications should be made on orms to be obtained from the xecutive Secretary, The Royal ociety, 6 Carlton House Terrace, ondon SW1Y 5AG, and returned by ecember 15, 1978. 8398(E)

COURSES/CONFERENCES LECTURES/SYMPOSIA

European
Molecular Biology
EMBO COURSE
ION-SENSITIVE INTRACELLULAR MICROELECTRODES
Bristol, England
June 25—July 8, 1979

The course is for 12 active esearchers who wish to learn how to se ion-sensitive intracellular microelectrodes. Participants will be taught ow to make, calibrate and do experiments with K⁺, Cl⁻, Na⁺ and pH⁺-ensitive microelectrodes. Most of their me will be spent in the laboratory, lthough there will be some lectures uring the course and a two-day ound-table discussion at the end. uring the round-table, a number of ading workers in the field will escribe their methods and recent sults Instructors will include Roger homas, Dave Ellis, Richard Vaughan-ones, Jochen Deitmer, Bill Moody nd Andrew Sharp.

Applicants should have some experience of electrophysiological techniques, nd have a convincing reason for aking the course. Applications should nclude a brief curriculum vitae ason for taking the course and a tter of recommendation.

Acceptance for course will be otified to applicants early in March articipants will have to pay their wn accommodation and subsistence penses (estimated at about £100), eir travel expenses and a Course egistration Fee of £30. One or two ants are available for applicants who an pay only their travel expenses ccommodation will be arranged by e course organiser.

Applications to Dr R. C. Thomas. epartment of Physiology, University Bristol, Bristol BS8 1TD, England, ust be received by February 19, 79. 8480(D)

COURSES/CONFERENCES/LECTURES/SYMPOSIA

FEBS ADVANCED COURSES

No. 58, "Biomolecular Electron Microscopy"
Ulm, F.R.G.,
29 March–7 April 1979

The Course, organised by A. K. Kleinschmidt, is intended to offer information on selected methods of biomolecular structure studies, and laboratory instruction in electron-microscopic methods of macromolecular analysis, to 40 qualified applicants Specialised fields, e.g electron microscopy of nucleic acids, membrane structure, nucleoprotein particles, immunocytochemistry, lipoproteins and proteoglycans, and autoradiographic procedures and image analysis methods will be included to participants' choice in laboratory practical sessions. Course fee, including accommodation and food: approx DM400.—Applications (by January 1, 1979) and info: Dr A K Kleinschmidt, University of Ulm, Department of Microbiology, Postfach 4066, 7900 Ulm, F.R G.

No. 60. "Gene Structure and Formation of RNA of Viruses and Animal Cells"
Israel, 15–21 May 1979

A workshop organised by Y. Aloni and co-sponsored by E.M.B O. Fee: $280.—Info· Mr Y. Berman, Congress Section, Weizmann Institute of Science, Rehovot, Israel

No. 62. "Genome Organization and Expression in Higher Plants"
Edinburgh, Scotland,
11–21 July 1979

A course for up to 125 participants Accommodation including full board, £120 approx Info. Dr C. Leaver, Dept. of Botany, The King's Buildings, Mayfield Road, Edinburgh EH9 3JH, Scotland

No. 56. "Membrane Proteins"
Berne, Switzerland,
10–22 September 1979

The course, co-sponsored by the Swiss Committee for Molecular Biology and organised by P. Zahler and A. Azzi, will consist of 1 week each of lectures and experimental work, and discussions The course will concentrate on specific problems of membrane proteins (solubilization, fractionation, isolation, characterisation, reconstitution). Places will be restricted to 80–100 for the lectures and to 40 advanced participants for the experimental part Fees (including registration, accommodation and food): Sw Fr 700 —for the full course or Sw Fr 340 —for the lecture course only. Applications should be addressed before April 1, 1979 to: Professor P. Zahler, Institut fur Biochemie, Universitat Bern, Freiestrasse 3, CH-3012 Bern, Switzerland.

No. 57. "Genetic Engineering"
Zagreb, Yugoslavia,
8–24 October 1979

Info: Dr V Šlamić, Institut "Ruder Boskovic", Post. pret. 1016, 41001 Zagreb, Yugoslavia. 8464(D)

FIFTH INTERNATIONAL SYMPOSIUM ON GLYCOCONJUGATES

A small number of grants are available to aid younger scientists resident in the U.K. to attend the above meeting to be held in Kiel, G.F.R., from September 2-8, 1979. For full information about the meeting and enquiries concerning the travel grants please write in the first instance, to either Dr R C. Hughes, National Institute for Medical Research, Mill Hill, London NW7 1AA or Dr R D. Marshall, Department of Chemical Pathology, St Mary's Hospital Medical School, London W2 1PG. Applicants should indicate briefly (100 words) their research interests. 8468(M)

INSTITUT NATIONAL DE LA SANTE ET DE LA RECHERCHE MEDICALE FRANCAISE
EUROPEAN MOLECULAR BIOLOGY ORGANIZATION

MOLECULAR AND CELLULAR ASPECTS OF OBESITY

AUGUST 27-29, 1979
NICE, FRANCE

The workshop is intended to bring together scientists actively working on different aspects of this topic. The number of participants is limited to about 60.

Sessions

1—Differentiation in culture of mammalian cells into adipocytes

2—Control of fatty acid synthesis and esterification in hepatocyte and adipocyte

3—Control of lipolytic activities in adipocyte.

Speakers (preliminary list)

G. AILHAUD (Nice)
A. W ALBERTS (Rahway)
P. BELFRAGE (Lund)
R. M. BELL (Durham)
P. BJORNTORP (Goteborg)
D. N. BRINDLEY (Nottingham)
R. M. DENTON (Bristol)
H. GREEN (Cambridge—USA)
D. LANE (Baltimore)
T OLIVECRONA (Umea)
D. A K. RONCARI (Toronto)
O. ROSEN (New York)
T. RUSSELL (Miami)
P. THOMOPOULOS (Créteil)

Communication and Poster Sessions

An invitation to submit communications or posters is extended to all prospective participants.

Applications

Applications may support their applications by including one or more of the following: a list of recent publications, an abstract for a communication or for a poster, a brief summary of the applicant's interests in this area. Applications should be sent before April 15, 1979 to:

Dr G. AILHAUD
CENTRE DE BIOCHIMIE
FACULTE DES SCIENCES
Parc Valrose
06034 NICE—(FRANCE)

Applicants will be notified of acceptance by May 31, 1979.

Registration

There will be no registration fee. The organization will cover accommodations and full board Sessions, meals and lodging will be at College International de Sophia-Antipolis (Nice). 8484(K)

IMPERIAL CANCER RESEARCH FUND DNA TUMOR VIRUS MEETING 1979
CHURCHILL COLLEGE CAMBRIDGE, ENGLAND
July 16-20, 1979

The Meeting will be on the molecular biology of small DNA tumour viruses, particularly polyoma, SV40 and adenoviruses and is open to anyone interested in the subject. The scientific programme will include oral presentations and posters.

The cost for registration, accommodation, food and the abstract book will be approximately £100. Travel money can only be provided in a few, very exceptional circumstances.

Anyone interested in attending the meeting should apply immediately for further details to 'The ICRF DNA Tumour Virus Meeting Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX, England.

8360(C)

A NATO SCHOOL
on
TOPICS IN THEORETICAL ORGANIC CHEMISTRY

will be held in Gargnano (Garda Lake), Italy on June 18-30, 1979

Lectures will be delivered by.

A. Bernardi (Italy);
E. Clementi (Italy);
I. G. Csizmadia (Canada);
N. Epiotis (U.S.A.);
P. von R Schleyer (Germany)

Intending participants should contact.

A
MEETING
ON
RECOMBINANT DNA

Organised by the Committee on Genetic Experimentation (COGENE) of the International Council of Scientific Unions and the Royal Society of London and will be held at Wye College, Kent, from 1-4 April 1979. The purpose of the meeting is to review the current status of recombinant DNA research and technology and to discuss matters of concern such as support for the research, its regulation through guidelines and legislation, and the eventual practical application of the technology.

Representatives of national recombinant DNA committees and other involved national and international organisations are being invited but a small number of places are being reserved for general applicants.

The registration fee for the Conference is US $80 or £40. The charge for accommodation and full board is US $120 or £60.

Those wishing to participate should write for a registration form and further details to The Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, England.

8446(C)

NATO INTERNATIONAL SUMMER SCHOOL
"TRANSFER OF CELL CONSTITUENTS INTO EUKARYOTIC CELLS"
SEPTEMBER 2-14, 1979—PORTUGAL

Lectures and discussions **in English** will cover the following topics:

(1) Evaluation of experimental systems to transfer macromolecules into animal and plant cells.

(2) Genome organisation: (i) Expression of cloned DNAs injected into oocytes (ii) Genetic engineering in plant cells.

(3) Fidelity of transcription and translation: (I) Injection of DNAs, RNAs and tRNAs into oocytes and somatic cells

(4) Cell transformation and tumorigenicity: (i) SV40 model; (ii) In vitro traits that correlate with transformation.

(5) Transfer of nuclei and chromosomes into whole cells and cell hybridisation: (i) Mapping of eukaryotic genes; (ii) Control of cell differentiation.

(6) Targeting of drugs and macromolecules with liposomes

The lecturers will include: M. L. Birnstiel (Switzerland), M R. Capecchi (USA), J. E. Celis (Denmark), T. Ege (Sweden), G. Gregoriadis (England), A Grässmann (West Germany), G. Marbaix (Belgium), A. Loyter (Israel), D. Papahadjopoulos (USA), M Rechsteiner (USA), F. H Ruddle (USA), J. Schell (Belgium, J V. Small (Austria), D W. Stacey (USA), K. Willecke (West Germany), J. Zeuthen (Denmark).

The summer school will be suitable for predoctoral students and for postdoctoral workers in related fields.

Applications should be sent to Dr J E. Celis (Deparment for Biostructural Chemistry, Intitute of Chemistry, University of Aarhus, Langelandsgade 140, 8000 Aarhus C, DENMARK) no later than March 1, 1979 They should contain a curriculum vitae, including the applicant's scientific background and interests, and one letter of recommendation. There is no special application form.

The applicants will be informed before April 15, 1979, whether they have been accepted. An accommodation fee of US$125 will then be required. Participants will have to cover their own travel expenses as well as pay for lunch and evening meals. Accommodation will be arranged by the organisers

The organising committee: J. E. Celis, Chairman (Denmark), A. Grässmann (West Germany), M. C. Lechner (Portugal) and A. Loyter (Israel). 8469(D)

Microbiological Research Establishment

Enzymes for Clinical Laboratory Use

Broad spectrum beta-lactamase
50 × 1000 units in VIALS @ £75.

A sterile, lyophilised mixture of 4 enzymes which has activity against a wide range of penicillins and cephalosporins, including cefuroxime.

In addition to beta lactamases I and II from **Bacillus cereus,** it contains enzymes derived from **Enterobacter cloacae** and **Escherichia coli.**

It is suitable for inactivating beta lactam antibiotics in samples of blood and other body fluids.

Gentamycin acetyl transferase
50 × 2 milliunits in VIALS @ £100

A lyophilised product derived from a strain of **Escherichia coli.**

It is suitable for determining aminoglycoside antibiotics including amikacin, gentamycin, kanamycin, neomycin and tobramycin in the presence of other antibiotics.

Glycerokinase
5000 units @ £100.

This product is supplied as a suspension in 3.2M ammonium sulphate (1000 units*/ml, 100 units*/mg protein).

It is derived from **Bacillus stearothermophilus** grown at 55 and is very much more thermostable than the enzymes derived from **E. coli** and **C. mycoderma.**

It is suitable for the determination of serum triglycerides.

*Units defined at 30

3-Hydroxybutyrate dehydrogenase
200 units @ £100

This product is supplied as a suspension in 3.2M ammonium sulphate (16 units/ml, 19 units/mg protein).

It is derived from **Rhodopseudomonas spheroides** and is used for the determination of ketone bodies.

Prices include packing and delivery. UK orders are subject to VAT at ruling rates. Send your order to the Microbial Products Section, Microbiological Research Establishment, Porton, Salisbury SP4 0JG, Wiltshire, UK.

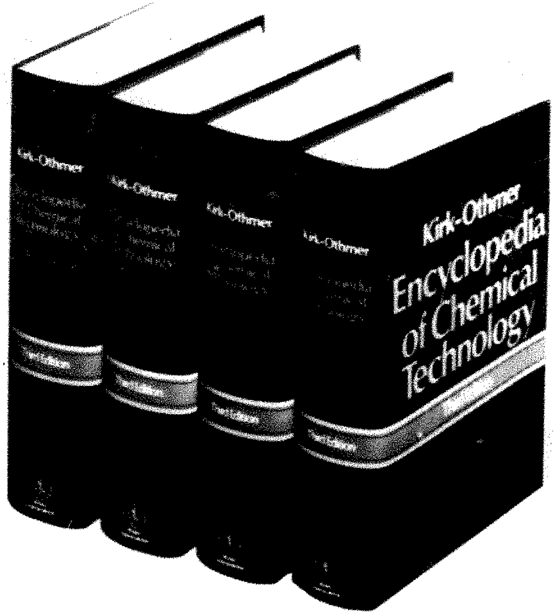
"impressed with the quality"–*Chemical Engineering*
"Invaluable...authoritative"–*Chemical Processing*
"wide ranging...packed with goodies"–*New Scientist*



The third edition of the **ENCYCLOPEDIA OF CHEMICAL TECHNOLOGY** is built on the solid foundation of the previous two editions. All of the articles in this new edition have been rewritten and updated and many new subjects have been added to reflect changes in chemical technology since the second edition. The results, however, will be familiar to users of the earlier editions: comprehensive, authoritative, accessible, lucid. This Encyclopedia remains the indispensable tool for all producers and users of chemical products and materials.

In many ways, this edition is an entirely new encyclopedia–yet its format is familiar to those acquainted with the earlier editions. New features include the use of SI units as well as English units, Chemical Abstracts Service's Registry Numbers, and a complete indexing based on automated retrieval from a machine-readable composition system.

New subjects have been added especially in polymer and plastics technology, fuels and energy, inorganic and solid state chemistry, composite materials, coatings, fermentation and enzymes, pharmaceuticals, surfactant technology, fibers, and textiles. As in the Second Edition, authors are acknowledged at the end of every article.

Culturing cells?

Would you like a cell culture technique which gives you higher cell yields for less effort, less time and less money?

You should know more about microcarrier culture with

Cytodex™ 1

- High cell yields
- Much smaller working volumes
- Easy control and monitoring of cultures
- Simple harvesting of cells without centrifugation
- Saves you space, effort, time and money

One gram of Cytodex 1 gives you the same capacity for cell growth as 7 roller bottles or 76 standard Petri dishes.

Cytodex™ 1 – the new dimension in cell culture.

Ask for more information today, and prove it for yourself.

Royal Society Esso Award for the Conservation of Energy

For the second consecutive year the Royal Society Esso Award for 1978 has been awarded to a group of five.

Due to their efforts in developing the Prototype Fast Reactor at Dounreay, the reactor has now been functioning safely and effectively since 1976. It has achieved a very notable increase in the efficient use of nuclear fuel and has a generating capacity equal, in one year, to that of 400,000 tons of oil.

The winners of the Award are Mr A. G. Frame, Mr J. M. Laithwaite, Mr A. D. Evans, Dr J. F. W. Bishop and Dr T. N. Marsham.

Previous awards have been made for work on corrosion in power stations, the development of an electronic system that computes optimum start and shut-down times for heating systems in individual buildings; work in the developing field of solar energy utilisation; and the application of gas turbines to total energy systems in industrial plants.

The Royal Society Esso Award for the Conservation of Energy was instituted in 1974 and consists of a gold medal and a prize of £1,000. It is awarded for outstanding contributions to the advance of science, engineering and technology leading to a more efficient conversion or use of any form of energy. Nominations for the 1979 Award are required by 7 February 1979.

Circle No. 06 on Reader Enquiry Card.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,** 1 (1975) and **264,** v, 11 Nov. (1976).

T cell origin of human macromolecular insoluble cold globulin — *S. P. Hauptman and E. Kansu* 393
Mode of coupling between hormone receptors and adenylate cyclase elucidated by modulation of membrane fluidity — *G. Rimon, E. Hanski, S. Braun and A. Levitzki* 394

Prejudicial to the interests of the state?

FOR nearly eighteen months the British courts have been occupied in one way or another with the cases of Crispin Aubrey, Duncan Campbell and John Berry, who had been accused of various breaches of the Official Secrets Act. Mr Berry is a former analyst in an overseas signals intelligence unit, and Messrs Aubrey and Campbell are journalists who recorded a three-hour conversation with Mr Berry on the subject of signals intelligence in February 1977. Immediately after the conversation all three were arrested.

A variety of charges were directed at the defendants, most notably under section 1 of the 1911 Official Secrets Act which prescribes up to 14 years in prison for those convicted of passing information for a "purpose prejudicial to the safety and interests of the state". Past prosecutions under this section have been confined to cases of espionage and sabotage; the purposes of the defendants seem to have been limited to the dissemination of information through journalism so a conviction would certainly have broken new ground in interpretation of the act. In the event, as proceedings wore on, with many peculiar asides down to the revelation that the foreman of one jury was himself a former soldier with the highly secretive Special Air Services Regiment, the Section 1 charges were dropped and the defendants were only accused under Section 2 of the act, which makes it an offence simply to transmit or receive any unauthorised information about what government employees do, see or make. Success for the prosecution under those circumstances was inevitable; there cannot be a single self-respecting journalist, nor for that matter government employee, who could not be prosecuted under Section 2 for some indiscretion or other. The judge, having earlier hinted that he did not intend to impose immediate prison sentences, lived up to his promise, sentencing Mr Berry only to a suspended six months in gaol and providing Messrs Aubrey and Campbell with conditional discharges.

It is important that this case be remembered for more than its elements of farce and anticlimax, and in particular a perspective has to be recognised on the wider issues involved. True, Mr Berry did pass on rather low-grade information concerning secret activities of the British government in the accumulation of intelligence—information which, it is claimed, is in any case almost in the public domain. And true there must be some small aspect of a government's activities which, for the sake of national security, is best not widely known (though Mr Berry's revelations do not seem, in any sense, to fall into such a category). But is it worth a quarter of a million pounds of public money to try and crush perpetrations of peccadilloes which could have been dealt with summarily in a magistrates' court? Maybe the judge's lenient sentences will have put heart into those who wish to reform our whole attitude to secrecy in government—a long-delayed activity. More likely the heavyweight support the government has shown for the maintenance of a *cordon sanitaire* around its activities will encourage those in government service who hold the view that nobody outside a charmed circle should know anything at all.

The Official Secrets Act casts a very long shadow. The same act that says it is undesirable that the current whereabouts of Britain's nuclear submarines should be widely known also says that any difference of opinion within a government agency is not for outside consumption. And the penumbra is even larger; those within the confines of the Officials Secrets Act are expected to develop a profound group loyalty which regards even such a harmless thing as a joking reference in print to the organisation as meriting official displeasure.

The results of decades of obsessive British secrecy and the harbouring of inside knowledge are around for all to see. In the Western world there cannot be a single government less open in its intentions with the public, and more distrustful of those, like journalists, whose profession is not just to repeat the official line but to try and shed light on the inner processes of decision-making. And the lack of easy flow of qualified people into and out of government service just reinforces the insider mentality. It is a total change of attitude, not a rewriting of the Official Secrets Act, that is needed to open up government—and this may take a generation. But by its vigorous pursuit of minor journalistic escapades the British government has shown it doesn't yet recognise the need for change at all. □

Inflation–and Congress–kill growth in funds for basic science

President Carter has had difficulty persuading Congress to increase support for basic research. Next year promises to be even harder. **David Dickson** reports.

Now that the dust is beginning to settle, it appears that apart from biomedical research President Carter has failed to deliver one of the promises made in his budget request to Congress for the financial year 1979, namely a "real growth" in funds for basic science.

The President had asked for a total of $3.6 billion, which would have resulted in an overall funding level 5 per cent above inflation. But the request has fallen victim to two factors: a higher-than-expected inflation rate, and a Congress reacting strongly to grass-roots demands for general reductions in federal spending.

Both factors continue to dominate planning for the 1980 budget, which will be announced in January. And despite indications from the president that he wants to see basic research protected from the most severe cuts, few expect that it will receive any particular privileges, or escape from the general constraints being imposed.

Speaking at a news conference earlier this month, for example, the President merely said that: "I have directed in the preparation of the 1980 fiscal year budget that basic research and research and development in general *should not be reduced as a percentage of the total federal budget*" (emphasis added).

The precise effects of Congressional actions on the science budget over the past year have yet to be officially calculated. The one bright spot—which tends to make the overall picture appear better than it really is—is a 34 per cent increase in the funds available for basic biomedical research through the National Institutes of Health.

Apart from this, officials of the American Association for the Advancement of Science have calculated the funds for basic science in all other fields will be 9.3 per cent higher than 1978. Dr Richard Atkinson, director of the National Science Foundation, gave a figure last week of 8.3 per cent; and others expect the figure to be even lower—close to the inflation rate.

The result has been a major disappointment to the scientific community. "The President's request for real growth in the science budget was met with great delight by the academic community; we are obviously disappointed by the lack of significant real growth in the budget", Dr Gerald Lieberman, vice provost and dean of research at Stanford said last week.

Overall, funds for research and development have not done too badly. The President asked Congress for an increase in R&D expenditure of 6.8 per cent, to a total of $29.3 billion. This figure was increased by Congress by a further $315.5 million, the major growth occurring in the Department of Energy, and the Department of Health, Education and Welfare (which funds NIH).

Furthermore, not all requests for increased support for basic science were handled roughly by Congress. There was general support for new research in the energy sciences, for example. Many Congressmen have been impressed by the performance of Dr John Deutch as director of the Office of Energy Research.

Similarly the budget for the National Aeronautics and Space Administration emerged relatively unscathed. The two main casualties were the proposed search for extraterrestrial intelligence, and continuing research on lunar samples brought back by the Apollo missions; however major new starts, such as the solar–polar satellite and the earth radiation budget satellite, remained intact.

The two agencies to suffer most were the National Science Foundation and the Department of Defense. The former had been slated by President Carter for an increase in basic research funding of 9.7 per cent; it ended up with an increase estimated by NSF director Richard Atkinson as 5.6 per cent, well below the expected level of inflation (although still, according to NSF officials, better than some had feared.)

Finally Congress responded unsympathetically to administration requests for an increase in expenditure for military-related research. The Senate, for example, although indicating that it might be prepared to consider increases in existing university-based programmes, rejected a proposal to start a new "Defense Science and Engineering Programme" for university research which would have been allocated $9 million in 1979 and $27 million in FY 1980.

The administration had been hoping that some of the research items cut from the DoD budget could be included in a supplemental request now being prepared following a presidential veto of the final defense appropriations bill, which included provisions for building an extra aircraft carrier unwanted by President Carter. However both Senate and House committees are reported to be unsympathetic towards such a move, arguing that such requests should be placed in the 1980—rather than the 1979—budget.

The net result of the various Congressional actions is what Dr Norman Hackerman, chairman of the National Science Board, has described as a "letdown feeling" among members of the scientific community.

Basic research, by agency (**$millions**)

	1979 Budget	Congress Approved	Change	% From Budget	% From 1978
NIH	856.0	1,019.0	+163.0	+19.0	+33.6
Other HEW	133.1	123.5	− 9.6	− 7.2	+28.1
NSF	754.9	741.9	− 13.0	− 1.7	+ 7.8
NASA	519.8	513.1	− 6.7	− 1.3	+ 9.6
Energy	467.5	465.5	− 2.0	− 0.4	+ 7.6
Defence	363.9	354.7	− 9.2	− 2.5	+10.8
Agriculture	251.9	256.2	+ 4.3	+ 1.7	+ 9.0
Interior	164.3	164.3	—	—	+ 4.6
Commerce	31.7	30.4	− 1.3	− 4.1	+10.9

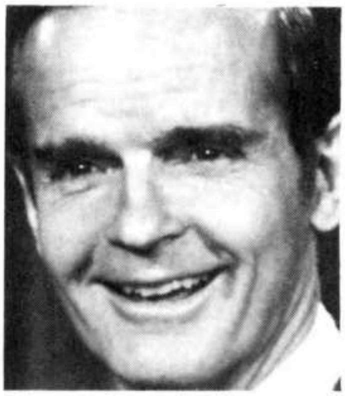
Others	30.6	30.6	—	—	+10.1
Total basic research	$3,636.7	$3,756.2	$+119.5	+3.3%	+15.0%

From the AAAS report "Congressional Action on R&D in the FY 1979 budget".

●**Representative Whitten: "no friend of basic science"**



●**Senator Proxmire: "scourge of the scientific community"**

0028–0836/78/0276—0308$01.00

As far as next year is concerned, things look little brighter. The President has repeatedly stressed the importance he attaches to supporting basic science to guarantee the long-term health of the country. In his nation-wide anti-inflation speech of 24 October, for example, he said that despite other budgetary constraints, "federal support for research and development will continue to increase, especially for basic research".

Some observers in Washington feel that the budget request for 1980 will propose a growth rate for basic science of 2 to 3 per cent above the expected inflation level. They take comfort, for example, from the fact that one of the first visits paid by Mr Alfred Kahn, the President's chief inflation fighter, was on Dr Frank Press, director of the OSTP, to confirm that he agreed with Dr Press' emphasis on the importance of research and development for long-term national prosperity.

The great unknown is Congress. This month's elections sent a clear message to Washington: US electors are demanding greater prudence in the way that the federal government spends its money and popular support gathers rapidly for those seen willing to yield a budget-cutting knife

As far as authorisation bills are concerned (those that represent policy decisions about the future directions of science) there is not likely to be too much problem. The new chairman of the House Science and Technology Committee will probably be Representative Don Fuqua of Florida, who has worked closely with agencies such as NASA in the past (and has several major research universities in his state).

Similarly the fortunes of science authorisation in the Senate are likely to remain in the relatively sympathetic hands of Senators Edward Kennedy and Adlai Stevenson Jr.

Appropriations committees, however—those that agree to disburse the funds—are a different story. In the House, the retirement of Representative George Mahon as chairman of the appropriations committee means that the position may be taken by Representative Jamie Whitten of Mississippi, the next in line on grounds of seniority

Mr Whitten is no great friend of the basic science community, or of its peer review system. This year the appropriations subcommittee of which he was chairman rejected an administration request for $30 million for a competitive grants programme for agricultural research in the 1979 budget, an attempt to shift away from the present system by which research funds are handed out to state land-grant colleges on a pro rata basis.

Defending this cut—half of which was later restored in the conference with the Senate—Mr Whitten said: "Congress must not allow itself to be placed in the position of being held accountable to the people for their research priorities established by a non-elected bureaucrat issuing grants to his fellow scientists". And his subcommittee's report contained detailed directions on how agricultural research money should be allocated

It is the Senate appropriations committee, however, which is giving the scientific community the greatest cause for concern, in particular over the implications of the loss of Republican Senator Edward Brooke

The chairman of the subcommittee responsible for passing both NSF and NASA funds is Mr William Proxmire, scourge of the scientific community with his infamous "Golden Fleece" Award for esoteric sounding research. (It was Senator Proxmire, for example, who was responsible for deleting most of the lunar sample analysis from NASA's 1979 budget).

Proxmire strengthened

The results of the elections have strengthened Mr Proxmire's hand. Last week he said "The fiscal scalpels must be applied to both military and civilian programmes, foreign and domestic spending, and to the sacred cows of the powerful economic interests . . No program, no interest group, and no region of the country, should remain immune to tough, detailed, and in depth budget cuts."

Up to now, Mr Proxmire's attempts to restrict funding for basic research has encountered strong—and frequently successful—opposition both from Mr Brooke, and from the ranking Republican member of the sub-committee, Senator Charles Mathias of Maryland.

However following Senator Brooke's departure, Senator Mathias is reported to be considering moving to a different subcommittee, and the concern of scientists that such a move could leave both NSF and NASA highly vulnerable has been heightened by the news that the subcommittee's minority staff member and aide to Senator Mathias, Mr Bob Clarke, is leaving the Senate to enter private law practice.

Much, of course, remains unknown about the future membership of committees, and will not be definitely resolved until Congress reconvenes in January. However one of the lessons brought home by the last Congress was the increasingly significant role played by intensive lobbying efforts.

Part of the substantial increase in support for basic biomedical sciences seems to have been due to a widely-publicised visit to Washington at the beginning of the year by a group of eminent biomedical scientists. In both public hearings and private meetings with Congressmen and their staffs, members of the group, which included three Nobel laureates and the heads of some of the leading US research institutions, argued that the long-term understanding of disease required a shift from a "disease of the month" mentality to a greater concern for basic science problems.

These arguments were subsequently reflected in Congressional action on the NIH budget Funding for cancer research, traditionally a recipient of Congressional largesse, was increased by 6.8 per cent; in contrast, the research budget of the National Institute for General Medical Sciences was raised by 25 per cent, to a total of $231 million Particularly significant was the emphasis placed in Congressional reports on the need to support "investigator initiated" projects, a point repeatedly stressed by the visitors to Washington, and the increase in funding for the Biomedical Research Support Grants programme.

A further illustration of the value of direct lobbying was memorandum sent by President Carter in June to the heads of appropriations committees and subcommittees requesting that they respect the integrity of the R & D package in his budget request Although the success of the memorandum was limited, some feel that it helped limit damage to the budget of, for example, the NSF

One message seems clear. Despite widespread awareness of the economic importance of research and development, the scientific community no longer enjoys any privileged position with respect to members of Congress, but must argue with everyone else for a share of the cake. "The universities, scientific societies and even industrial organisations will try to do even more than this year to increase support for research", Dr Jack Crowley, of the Association of American Universities, said last week

It remains to be seen whether President Carter's concern for the health of basic science is any more successful next year than this. Certainly his public statements, and the close relationship which his scientific advisers have been able to build up with the Office of Management and Budget, have reassured the scientific community that, unlike some of his recent predecessors, they now have an ally in the White House.

But since much of the science budget is in the form of nonmandated expenditure (unlike, for example, social security and Medicare), it remains highly vulnerable to marauding budget cutters. And it will take more than fine words and noble sentiments to secure any real growth for basic science in the immediate future. ☐

Post-docs take up ARMS

Short term research contracts are leading scientists to rebel, writes **Joe Schwartz**

THE organisation of scientific research in the UK has evolved to the point where there are now 10,000 people employed to do research on short term contracts and an additional 1,800 PhDs registered as unemployed with the Department of Employment. Combine these figures with recent cuts in public spending and the result is the inevitable development of labour-management conflict in an area of the economy that has always considered itself immune from such pressures. And, wherever a management view in defence of short term contracts is articulated (contracts are for specific pieces of work, the scientific mind burns out early in life, unfruitful research lines can be easily terminated), there is a labour point of view articulated by short term contract workers themselves.

ARMS, the Association of Researchers in Medical Science, is one organisation that is attempting to speak for the needs of full time researchers employed in the nation's hospitals and medical schools on short term contracts.

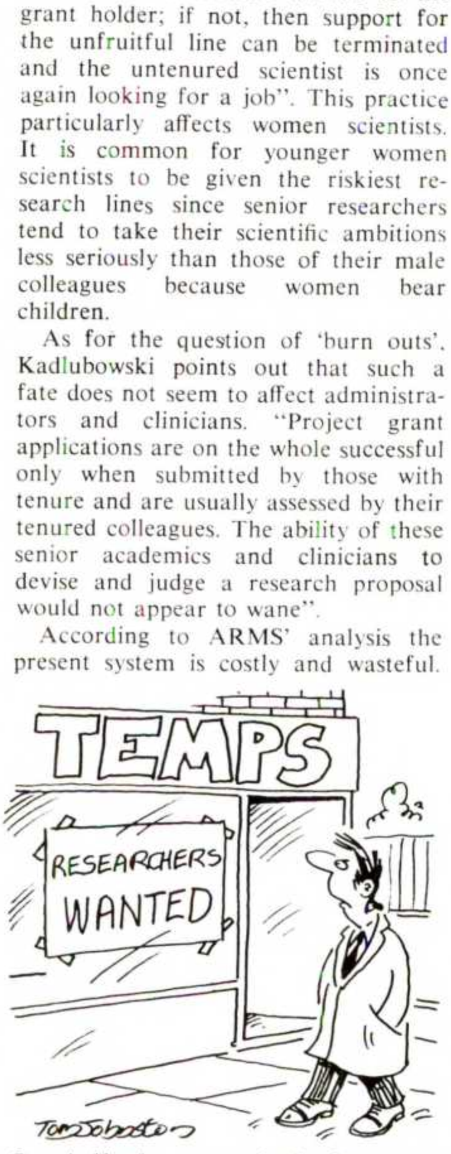
Based at Guys Hospital in London, ARMS was formed after a series of public meetings in July 1978. Its principal goal is to establish a career structure for full time non-teaching researchers analogous to university lectureship scales. Although not ruling out trade union affiliation, the organisation at present intends to negotiate with employers and to do educational work in an effort to change the present arrangements.

Membership in the organisation received a boost in September when the University of London which administers Guys instituted waiver clauses in short term contracts. Seeking to prevent 'onerous benefactions' to the research staff, the university demanded that researchers relinquish their rights to redundancy pay and claims against unfair dismissal. The outcry against this particular action has cast the university into the role of a 'bad' employer and could be rescinded if the researchers are able to maintain an active resistance to the measure. Brian Davis, Labour MP for Enfield and a member of the MRC, acknowledges that the MRC would like 'maximum flexibility' in its hiring and firing but is working to abolish the waiver clause as soon as possible. The Cancer Research Campaign, located at Mt Vernon Hospital, has removed the waiver clause after protests from the researchers there.

The waiver clause, however, is only the most recent grievance. Dr Mick Kadlubowski, Information Officer of ARMS, regards administrators' arguments in favour of contract work as specious and self serving. "The system prevents the untenured full-time researcher from having an effective say in research policy. Should a project be successful the honours accrue to the grant holder; if not, then support for the unfruitful line can be terminated and the untenured scientist is once again looking for a job". This practice particularly affects women scientists. It is common for younger women scientists to be given the riskiest research lines since senior researchers tend to take their scientific ambitions less seriously than those of their male colleagues because women bear children.

As for the question of 'burn outs', Kadlubowski points out that such a fate does not seem to affect administrators and clinicians. "Project grant applications are on the whole successful only when submitted by those with tenure and are usually assessed by their tenured colleagues. The ability of these senior academics and clinicians to devise and judge a research proposal would not appear to wane".

According to ARMS' analysis the present system is costly and wasteful.



One half of a researcher's time on a short term contract is spent settling into the project and then towards the end looking for a new job. After two or three contracts, the researcher is 30–35 years old and the contractors begin to find the price of experience too great. The experienced researcher is told to seek employment elsewhere and the funds thus 'saved' are used to boost the intake of juniors. "How can science progress when hard-won experience is so callously thrown away", asks Kadlubowski.

Davison of ASTMS; Akker of AUT.

ARMS has approached the DES and the MRC with little effect. Dr Anne Simmonds, chairperson of ARMS, is scathing about a recent MRC grant scheme: five-year renewable grants to age 35, grants to permit tenured academics to do full time research for a short time, and external full time research professorships for the clinically qualified. "At this critical time with their scant funds and these alarming unemployment statistics," she says "the MRC comes up with funds to allow the tenured time off to dabble in full time research, the clinician the opportunity to return to the field and progress without restraint to the professorial level, and another ten years of insecurity offered to the non-medically qualified."

The action of the MRC in totally ignoring the most urgent problems, the scandalous plight of full-time non-medically qualified researchers despite representations from clinical professors, deans of medical schools and the scientists themselves is utterly reprehensible".

Anne Simmonds is equally critical of university administrators. "Instead of raising their voices in support of some urgent action to resolve the situation they are aggravating it by looking for loopholes in the law to enable them to escape any commitment to their full-time researchers whatsoever."

Faced with this response from employers ARMS members have contacted ASTMS and the AUT, the two trade unions involved. "ASTMS calls us elitist and they want money on the line before they'll do anything", say members of the executive committee. Stan Davison, assistant general secretary of the 460,000-member ASTMS, denies this charge but admits that the problems of organising short term contract workers are formidable; the workforce is spread out over the entire country in small pockets of twos and threes; many scientific workers are indifferent or even hostile to trade unions; and research workers tend to be inexperienced and sympathetic to management arguments.

ASTMS is opposed to short term contracts and the unregulated em-

Dr Joseph Schwartz is on leave from City University, New York.

0028–0836/78/0276—0310$01.00

ployer-employee relationship that currently prevails. Philip Hounsell, division organiser for ASTMS at Guys Hospital welcomes an organisation like ARMS. Hounsell feels that only by rank and file organising at the local level can sufficient strength be built to have a real effect. Both Davison and Hounsell emphasise however that without proper trade union organisation and support it is doubtful whether the authorities can be persuaded to act.

The 30,000 member AUT is approaching the problem at a higher level. It has negotiating rights for the universities and successfully negotiated national salary scales for researchers in 1975. John Akker, deputy general secretary, says that the AUT handles "scores of cases" of senior research workers, many with international reputations who have been made redundant at the age 40–45. The hardship is even worse he says because "many people are so specialised as to be unemployable".

The AUT offers legal services to members faced with dismissal and has been able to negotiate cash settlements in many cases and is in the process of formulating a code of practice for the employment of research staff. The AUT is attempting to move its efforts into the ministerial arena. "The MRC claims that the universities are the employer and the universities say since the MRC provides the money it is up to the MRC to sort it out", says Akker. Even if the research councils were to become actively involved there are still 78 autonomous institutions to deal with. The AUT wants the government to convene a committee with trade unions, universities, research councils and government representatives on it.

Whether the government is prepared to take on the issue is unclear. Certainly the universities are acting as if they have just discovered 19th century labour relations. Insisting on the value of piece work places academia in the league of garment manufacturers in a pre-trade union situation. This sensibility is reproduced in many researchers themselves who accept the line that a good student can always find a position and who reject trade union protection as being unprofessional.

But since research is an integral part of a modern economy some pressure exists for researchers to be able to make some changes. Certainly young potential scientists will begin to reject a scientific career if they become aware of the true conditions of research work. And there is nothing to prevent out of work scientists from organising just such a campaign if they are angry enough. ☐

People before pounds, say SRC

BRITAIN'S Science Research Council is no longer so worried about money, but is finding itself with another problem: manpower. The chairman of the SRC, Professor Geoffrey Allen, said last week that "the manpower problem is preventing us from diversifying".

Professor Allen was presenting a fairly encouraging annual report for the year to April 1978. The budget reduction of 1.7% per year imposed on the SRC by the Advisory Board for the Research Councils had been held to 1%, and merely another £20 million over the next 4-5 years would make the SRC comfortable. A 2-3% increase in the 'science vote' (the money allocated to the ABRC by the government for disbursement to the research councils) would give the ABRC all that the ABRC thinks is needed nationally.

Professor Allen is taking the training function of the SRC very seriously, and hopes to introduce courses for "topping up" in new technologies. This is "the major issue now" in training. And he wants to introduce a five person "think tank" into the Council which will concern itself with improving the links between university and industry. This call for five new people underlines Professor Allen's concern for SRC manpower.

The development of new activities at the Rutherford and Daresbury laboratories, whose subnuclear physics accelerators were closed in the year under review, is also raising manpower problems. The SRC, like many other government bodies, is under a directive to reduce its manpower —in the SRC's case at 1% per annum. This would mean a loss of some 30 people per year; but with fairly young staff it is a hard target to reach through natural wastage and early retirement.

While it has been possible to retrain many of the displaced high energy physicists at Rutherford and Daresbury in subjects like energy research and computing, it is not so easy to turn a physicist into a biologist to run, say, a biology support team at the new synchrotron radiation source. The central problem is that a few key people are needed, with special talents, to implement the changes which Professor Allen would like the SRC to undergo. "We now need different types of scientists to maintain our central facilities and links with universities", says Professor Allen. The SRC is a potential employer of scientists. But at the moment it is being held back.

Skylark rockets could be made from spare parts say UK geophysicists

A GROUP of UK geophysicists has come up with an idea which, in the early 1980s, could help soften the blow on auroral physics of the Science Research Council's (SRC) cutback in 'big science'. It has suggested that component parts left over from the SRC's abandoned Skylark rocket programme could be used to build as many as twelve extra Skylark rockets.

The decision to abandon the Skylark rocket programme was taken in 1975-6 as part of the SRC's plan to economise on 'big science'. Since then the British Aircraft Corporation, the rockets' manufacturer, has been slowly winding down production. Only one rocket now remains to be launched from Woomera, Australia, next May. During the 21 years of the programme, more than 250 Skylark rockets have been successfully launched.

The UK rocket programme now depends on two small rockets, the 7.5 inch-diameter Petrel rocket capable of launching 14 kg to a height of 200 km and the 10 inch diameter Fulmar rocket capable of launching 50 kg to more than 250 km. These are used for studying the lower and mid-ionosphere.

The 17 inch-diameter Skylark rocket is capable of carrying about 150 kg to altitudes as high as 750 km. It is the only UK sounding rocket developed so far which is capable of investigating the structure of the upper ionosphere and the origin of auroral particles. Although a Fulmar might have the ability to fly high enough, it does not have the capacity to carry the instrumentation needed to measure energetic incoming particles and electric fields.

The geophysicists claim that twelve Skylarks of varying size could be assembled, furnished with payloads and launched at no extra cost to the SRC's planned rocket programme over the next ten years if they were launched in fours at three-year intervals. This would mean launching fewer Petrels and Fulmars; but the value of the Skylark is such that it is thought there will be little opposition. Just how much support the idea could gain is what the group of geophysicists is trying to find out at the moment. By late next Spring it hopes to have sufficient knowledge of the interest and the kinds of experiments which could be flown to put forward a concrete proposal to the SRC for funding.

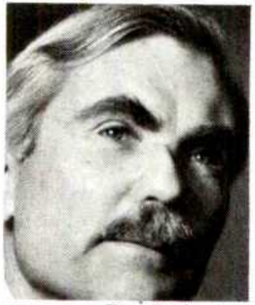
- **Nuclear waste disposal:** Highly radioactive waste from Britain's nuclear reactors could be safely stored underground by the 1990s, if suitable geological sites could be found, according to Dr Lewis Roberts (pictured below), director of Harwell research laboratory. In a lecture to the British Nuclear Society recently, he reviewed the present policy of the UK Atomic Energy Authority on radioactive waste disposal.

The means of solidifying high level wastes produced by the reprocessing of nuclear fuels, and the technology for building repositories, should soon be available, he said. At the moment, waste was stored as a highly radioactive acid solution in large tanks at Windscale. However, a solid was easier to contain and control than a corrosive liquid, so a technique for converting waste into a solid glass composition was developed at Harwell. This "vitrified" waste could then be placed in an underground store fitted with a simple cooling system and left, with minimum human surveillance, for the 500 years it takes for the highly radioactive actinides to decay.



An international programme, backed by the EEC, was underway to assess different sites for final storage, Dr Roberts said. Germany, Italy, Holland and Belgium were investigating the potential of salt and clay deposits, while Britain and France looked at hard crystalline rocks such as granite.

British exploration were running into trouble because some planning authorities (for example, in south-west Scotland and Northumberland) refused to allow the UKAEA to drill test holes. More research was needed to determine how safe the repositories would be, and the behaviour of containers and glasses under the conditions which might occur in storage sites. Despite these set-backs, Dr Roberts believed that research into final storage of radioactive waste should continue. The UKAEA was also looking into alternative storage sites, such as the oceans.

- **MPs seek comments on genetic engineering:** The social and political implications of the use of techniques of genetic manipulation, both in research laboratories and for industrial processes, are to be investigated in the UK by the Genetic Engineering Sub-Committee, which was set up by the House of Commons Select Committee on Science and Technology during the last session of Parliament.

The committee is asking any interested people or groups to submit written reports, even if they have not been specifically invited. The committee has also approached Government departments and agencies, professional bodies, companies and trade unions for reports on a wide variety of technical, commercial and ethical considerations. Submissions should be made before the end of the year, and the committee expects to report some time in 1979.

- **Chemical company claims dioxins a natural by-product of combustion:** The Dow Chemical Company, defending itself against charges that traces of chlorinated dioxins—one of the most poisonous of industrial chemicals—found in fish in the Tittabawasee River in Michigan had leaked from the company's pesticide plant, claim that its scientists have discovered the compounds to be natural by-products of combustion.

In what is said to be a "significant breakthrough" in the chemistry of fire, the company scientists say that small quantities of chlorinated dioxins, well below the level that poses a hazard to human health, have been discovered in coal and oil-burning power plants, in home fireplaces and in charcoal grills. "We now think dioxins have been with us since the advent of fire. The only thing that's different is our new-found ability to detect them", Dr Robert Bumb, research director of Dow's Michigan division, said last week.

The eating of fish from several rivers near the plant was banned by state and federal environmental agencies earlier this year following the discovery of traces of chlorinated dioxins in both soil samples and game fish.

- **Petrol additive found to be potent carcinogen:** A chemical widely used as a petrol additive and a fumigant for agricultural crops has been found to cause a "high incidence" of cancer in laboratory animals by the National Cancer Institute. According to the institute, tests have shown ethylene dibromide (also known as EDB or 1,2-dibromoethane) to be one of the most potent animal carcinogens ever found, and must be considered capable of causing cancer in humans.

The National Institute for Occupational Safety and Health has estimated that in 1977 about 9,000 workers were exposed to EDB in industrial settings, and that a further 650,000 service station attendants were exposed to much lower levels of EDB. The chemical is added to tetra-alkyl anti-knock fluids to remove lead from the engine's combustion chamber.

In a two-year study, during which large doses of EDB were administered to rats and mice, stomach cancers developed in 58% to 90% of the rats and 56% to 94% of the mice, depending on the sex of the animal and the dose received. Some cancers developed less than two months after the beginning of the experiment, and the death rate among experimental animals was so high that the experiments were discontinued when the programme was only half-way through.

- **World population growth is slowing:** The rate at which the world population is growing has begun to slow down. Since the 1960s, birthrates have fallen by 15% in about half of the countries of the developing world, according to Rafael Salas, executive director of the UN Fund for Population Activities. However, Salas adds: "It would be unwise to conclude that the population problems of individual nations as a whole are at an end, or anywhere near it."

Another big world population rise is forecast, since at least 40% of the people of the Third World are under 15 and approaching child bearing age. In his annual report, Salas puts the lowest estimate for world population in the year 2,000 at 5.8 billion compared with today's total of about 4 billions. In poorer countries the age structure is changing towards a higher proportion of very young and very old people. The trend is causing concern at the UN, because it will put strain on economic and social resources for education and employment.

- **Naming the unifying gauge theories:** Some physicists are suggesting that the time has come to rename some of the new forces and interactions in particle physics. Greek, which was the basis for nomenclature until the arrival of modern idiosyncrasies such as "colour" and "flavour", could be used as the source for the new words, some physicists suggest.

The theoretical developments which appear to have unified the weak and electromagnetic interactions failed to

0028–0836/78/0276—0312$01.00

provide a new word that physicists could use to describe the forces, apart from the indirect term the "Weinberg-Salam model" and the unimaginative "electro-weak". A candidate for the title is "asthenic force", originally suggested by Chanowitz and Ellis and now revived in the October edition of the CERN Courier. *Asthenis* is a Greek adjective meaning "not strong", and so the word has the advantage of covering all phenomena not associated with the strong force. Chanowitz and Ellis suggested that the unified gauge theory of weak and electromagnetic interactions could be described as "quantum asthenodynamics". Pursuing their Greek source further, they proposed that the grand unified gauge theory of all the forces could be named "quantum holodynamics".

- **Lasers:** The laser light show in London's Oxford Street, the first of its kind to be used in Christmas decorations, was switched on last week, despite a safety inquiry which nearly banned the show. The six krypton and argon lasers have splitters to produce red and green beams of light. The system was originally built to sweep the laser beams along Oxford Street 20 feet above the ground. But the risk of a beam being reflected by a window into someone's eyes forced the Health and Safety Executive and Westminster Council to insist on the lasers being fixed in one position. The beams would be allowed to move only if every window along the route was blacked out.

'Problem' solving still claims Poland's scientists

"DESPITE many shortcomings which still exist, we have the right to state that our science is carrying out its tasks more successfully each year". So claimed Piotr Jaroszewicz, Prime Minister of Poland, speaking at the opening session of the Sejm (Parliament) last month.

For a head of state to present the Government's programme on science policy is somewhat unusual. Partly it may be attributed to what Jaroszewicz called the "particularly active part" which science must play in overcoming "the difficulties experienced by our economy at present" (disastrous results in agriculture for the fifth year running, difficulties in earning the hard currency needed for vital raw materials and over-consumption of labour-time, energy and raw materials).

Moreover, in September, Poland's trouble-shooting Minister of Science and Higher Education, Sylwester Kaliski, died after a car crash, and the presentation of the science programme by so eminent a figure as Jaroszewicz seems a further assurance of government commitment to the policy so largely associated with Kaliski's name, although originally worked out by the Polish Academy of Sciences —a structured hierarchy of R and D "problems".

In this scheme, problems vital to the economy range from "State problems", through "Key", "Interdepartmental" and "Departmental" down to "Branch" problems. The differences are both administrative (who is responsible for funding and coordination) and a matter of actual priority.

There are seven "State" problems at present—copper, coal, building industry, food, electronics, cancer and water/environment, and it seems likely that, in the near future, energy and the chemical industry will receive the same status.

The urgency of the "state" problems is considerable. In the case of building, the construction of a new campus for Poznan University has been approved and introduced into the central plan of the Government, with allocation of 4,500 million zloty. Yet, according to the pro-rector, Dr S. Kozarski, the University is having considerable difficulties in getting the construction under way, simply because of the overall state of the building industry.

According to a spokesman for the Ministry of Higher Education and Science, the system of problems is "working, though not so well as we had hoped at first". During the next five-year plan, he said, there would be greater freedom of decision-making left to the researchers and fewer referrals to distant committees in Warsaw. At present, the heads of research teams are far to circumscribed by "reports and byelaws".

Does this direction from above restrict academic freedom? No, said the rector of the Poznan Polytechnic, Dr Boleslaw Wojciekowicz, where some 60% of research comes under the central scheme. There is no compulsion, he said, for any institution to accept any problem it does not feel it can tackle. "Freedom of science", the rector exclaimed, "includes the taking on or not taking on of government research".

The system does serve as an indicator to research institutions what is important now and in the future, and provides a method of concentrating both personnel and financial resources. Moreover, any institution—his own Polytechnic, for example, can at any time propose some new problem to be included in the scheme. At present, he added, his Polytechnic acted as research coordinator for three such problems, at the "Interdepartmental" level, coming therefore, under the joint authority of the Academy of Sciences and the Ministry.

There also remains the other 40% of research activity at Poznan outside the central scheme. Some of this includes direct contract work for industry, but funds are still available for basic research direct from the Ministry of Education, and are distributed to the individual Institutes concerned. The Directors of these institutes have a fairly free hand in allotting these funds, and can finance any project they consider promising.

So far, too, international cooperation does not seem limited to the formal Government policy of Comecon cooperation. According to the Ministry spokesman, since Comecon is primarily an organisation for economic matters, the intra-Comecon links in higher education are somewhat weak. When there is joint research, it is directed not through the Ministry of Education but through the specialised ministries which have their own research institutes at their disposal.

Dr Wojchiekowicz put it more bluntly. "If the ministry proposes a key problem to us, we are not interested in whether another country needs it as well—though of course if we know others are working on it, we naturally try to establish contacts". His Polytechnic, he said, had collaboration agreements with 26 foreign institutes—including some in West Germany, Holland, France, and the USA. "But with non-Comecon countries, the basic problem is the perennial one of currency."

It would be strange, indeed, if the precious funding for foreign cooperation did not go first and foremost to government proposed problems, and, indeed, a number of examples could be cited. There is close cooperation with the UK on safety in coal mines, for example (coal is a "State" problem), while the "urban forest" conservation scheme (a "Key" problem) benefits from Landsat photographs under a

0028–0836/78/0276—0313$01.00

NASA–Polish agreement.

It would seem inevitable that this concentration on the coordinated problem concept should have its effect on the higher educational system generally. Jaroszewicz's policy speech proposed that "scientific and research topics of particular importance of the economy should be stressed even more not only at the research stage but in higher education also."

Likewise, the Ministry of Education spokesman indicated that future plans include "establishing closer links during study with productive activity". He also said that serious consideration was being given to the possibility of "reattestation"—the granting of professional qualifications not for life but for a limited period only, with renewal depending on the candidate's career in the meantime

Not surprisingly, perhaps, a number of academics are privately concerned about the ultimate effect of the problem concept on Polish science. The freedom to accept or reject a government proposal is, they feel, a somewhat circumscribed one. Academic freedom, they point out, was one of the principal issues of protest against the proposed constitutional changes in 1975-76. Although the ensuing "debate" resulted in a certain toning down of the clauses relating to Party preeminence, there still seems to be considerable nostalgia in certain circles for the concept of autonomous universities and academies electing their own senior officials without outside influence, instead of requiring, as at present, government and Party approval. **Vera Rich**

Leather science as alternative technology

by Paul Calvert

who is on leave from the University of Sussex

In developed countries it is easy, as a scientist, to adopt the view that most research stands a chance of being applicable and most applications of science will lead to an improvement in our overall well being. This is much less true in developing countries; given their labour surplus and shortage of capital any technological advance which replaces men with machines may be bad An example of a research organisation trying to serve a traditional, cottage industry is the Central Leather Research Institute (CLRI) in Madras.

The CLRI was set up under CSIR in 1952 with the task of providing scientific support to an industry which consists mainly of small factories and individual, often illiterate, craftsmen spread throughout India. An additional, uniquely Indian, dimension to the problem is that most of the workers are members of the "untouchable" castes Until 1971 the director of the institute was Professor Y. Nayudamma who subsequently became director-general of CSIR.

Writing in 1967 (*Science and the Human Condition in India and Pakistan*, edited by Ward Morehouse, Rockerfeller University Press, 1968) Nayudamma described the philosophy and operation of the CLRI. Much of the institute's effort is put into extension centres close to concentrations of the leather industry and extension workers who can visit and live in the villages. These workers must respect the skill of the village craftsmen and must be able to talk to them at a level they can understand. Thus a method for controlling *p*H during tanning would be presented simply as a series of coloured packets to be added at different times in the process.

Other programmes include a "guest tanner" who can visit and work in the institute, and monthly visits by the director, with local officials in tow, to the industry in a particular state. Institute staff have also been sent in to revive businesses which are running at a loss, the idea being that this can be a powerful demonstration of the benefits of science. CLRI is closely associated with the University of Madras and runs BSc and PhD courses in leather science as well as refresher courses for teachers from regional tanning institutes.

Since going to CSIR, Nayudamma has been able to develop his ideas of the role of science in India and has propounded them in two recent lectures. In a paper called "Endogenous development· science and technology" given at a UNESCO meeting in Paris in April, he discussed science and technology in developing countries In his eyes development is not simply a question of economic growth but of development of a people in terms of dignity, resourcefulness and social justice. Such patterns for development cannot be imported since they must suit the society in question.

Nayudamma quotes Gandhi's vision of self reliant, egalitarian rural communities using labour intensive methods and local resources but intellectually open and active Science, based as it is on experiment and reason, should reduce the hold of superstition and increase rationality and enterprise

Nayudamma sees imported technology as imposing the values and culture of the developed countries on the less developed. The success with which Japan imported technology is due to the strength of their indigenous technology which enabled them to modify the imported methods to suit their own needs So some non-imported route to technical development is needed in order that a level is reached at which constructive use may be made of imported technology This "alternative technology" has as its goals to provide employment, meet basic human needs and build confidence and self-reliance It would include use of local resources, recycling, have a low energy demand and would be a weave of traditional and modern methods

At the moment manufacturers tend to prefer imported processes which come fully developed, with known brand names as compared with local inventions which are untried and involve more risk. To overcome this, processes are offered with the government providing 50% of the risk capital and guaranteeing the result.

In "Developing Science for Development" a lecture at IIT in Madras last year, Nayudamma outlined the kind of research organisation he saw as necessary to serve a developing country. The key to science within this framework is one of setting clear goals for researchers At present they tend to be judged only on their status in international science so there is little encouragement for working on strictly local problems, particularly for scientists trained abroad

Further, scientists must be in close contact with the rural population; it is important to know the people whose problems you are solving and these are not the westernised elite but the rural majority with more basic needs This lecture was given at a time when CSIR was under threat of being broken up and apportioned amongst the various ministries, a good example, perhaps, of imported ideas (see *Nature* **270**, 89; 1977). Nayudamma strongly defends the existing structure which survived, and calls for a clear lead from the government as to what technology is needed When clear objectives are defined scientists usually achieve them.

In helping the leather industry CLRI must also tend to come into conflict with the caste system which is deeply ingrained in rural society In recent years the untouchable castes including leather workers have tended to move from the villages into the cities where they have more political and social freedom In the case of leather workers this will include setting up small businesses or co-operatives By becoming involved with small scale industry,

0028–0836/78/0276—0314$01.00

scientists thus also become very exposed to the ebb and flow of political forces.

Current fundamental research at CLRI, in addition to studies of tanning and degradation in leather, include extensive work on grafting synthetic polymers to collagen (*Makromol. Chem.* **175,** 729 (1974); *J. Polymer Sci.* **9,** 3199 (1971); *J. Appl. Polymer Sci.* **16,** 1975 (1972)) to produce wear resistance, water repellant and glossy surface finishes on leather. This sort of work is coming more into its own as India exports more finished as opposed to semi-finished leather. These treatments can be simply carried out and so are appropriate to small-scale industry. The institute also provides courses in design of leather goods so that the industry is able to keep up with fashions in world markets.

Thus CLRI provides an example of a scientific institute serving "alternative technology" and demonstrates the considerable effort that must be put into keeping communication open between the users and the scientists. Nayudamma, following his own precept that a director should return to the laboratory at the end of his term, is back at CLRI as a "distinguished scientist". He is studying the impact of CLRI on the leather industry over the last 25 years. The current director is M. Santappa who is also professor and head of the department of physical chemistry at the University of Madras. Santappa's main scientific interests before becoming completely involved at CLRI were in polymerisation of synthetic polymers.

The big question confronting this approach to science is whether a technically developing cottage industry could ever compete with heavily capitalised manufacturing industry. About 10 years ago much effort, particularly by Du Pont, was put into making artificial leathers consisting basically of a foam and skin structure of PVC. Had this succeeded, as it almost did, it would have drastically reduced the market for natural leather. In an industrialised society if workers lose their jobs under these circumstances they have a reasonable chance of getting others. Traditional craftsmen, such as Indian leather workers, do not have this flexibility, particularly if they are modernised to the extent that they depend on exported goods for their livelihood. □

Third World needs 'barefoot' science

How does a water tap work? **Michael Moravcsik** and **R. H. B. Exell** explain why knowing the answer can be a breakthrough for an African village.

The practical need for science in developing countries is rarely discussed. Debate usually rises to a general, analytical, or theoretical level. There is no question that such discussions help in understanding the role of science in those countries, and assist the proponents in convincing incredulous officials in national, international, and other decision making organisations, that science is necessary. And they also boost the morale of the scientists in the developing countries—who otherwise have many reasons for being discouraged and frustrated. But one should also be aware that the need for science can be much more down-to-earth.

In this brief note, therefore, we want to present a few examples where exposure to science as a way of thinking and as a method of inquiry and problem solving could play an important role in very simple everyday situations.

The examples are taken from "real life" situations that we have encountered during our stays in developing countries. Colleagues of ours could doubtless add dozens of such examples to the list.

Keeping cool: In urban buildings in tropical areas, built using modern techniques, the top floor is often unbearably hot. The reason is simple: the usually flat roof absorbs solar radiation, and no provisions are made to either insulate the roof from the ceiling of the top floor, or to design the building with a simple double roof with air space between the two for ventilation. Ironically, such features are often included in the traditional, older, and rural structures, but since the scientific reason for such features is not comprehended, builders cannot distinguish between those features of traditional architecture which are functional and those which are ceremonial or due to limitations of construction technology.

Keeping hot: In numerous developing countries tin-box ovens used on charcoal stoves are common. They simply consist of a usual thin-walled surplus tin-box, placed on top of a regular iron charcoal stove (similar to the hibachis popular in Western countries for use in backyard barbecues).

It does not take very much science to realize that the efficiency of such an oven, and also the attainable temperature inside, could be increased if all sides of the tin box except the one in contact with the stove were insulated. A little more science tells us that such a saving in fuel would be quite substantial, very rapidly returning the small initial investment in one of the available insulating materials.

Current problems: Electrical wiring in developing countries is often installed very flimsily and haphazardly, so that breaks in the wiring and other types of damage occur frequently. In such instances there are many accidents as well as further damage due to incorrect rewiring. For example, we have seen instances when the break in a two-strand wire was "repaired" by joining all four dangling wires in one knot.

Even the most qualitative and simplest *conceptual* understanding of current as a flow (and hence a schematic knowledge of what bears the unnecessarily forbidding title of Kirchhoff's laws) would do much toward preventing such occurrences.

Turning on: Recently, in one of the developing countries, the supply of tap water became quite intermittent for several months. It was then found that during those hours of the day when the water supply did not operate, much subsequent loss of water was initiated by taps being left in an "on" position during the time when the supply was off. People would try the tap, see that no water was coming, and then leave the tap without turning it to the "off" position. When the water supply re-

---

Michael Moravcsik is from the Institute of Theoretical Science, University of Oregon, USA; R. H. B. Exell is from the Asian Institute of Technology, Bangkok, Thailand.

0028-0836/78/0276—0315$01.00

turned, the water kept flowing sometimes during the whole day until somebody happened to return and turn it off.

Water being expensive, one of the important contributing factors in this apparent neglect is likely to be the complete absence of an image of a water flow with a tap being a gadget to transmit or obstruct this flow. When this simple point is not understood, there is no more "reason" for turning the tap to the "off" position when the water fails to emerge. This is science on such an elementary level that most of us might find it difficult even to realise that it is science.

Roofing in the tropics: applying simple scientific principles can make a hot house cool.

Counting squares: The next two examples are perhaps more mathematical than physical, but they again stress the importance of understanding concepts rather than following recipes.

A junior lecturer at a university, engaged in an "applied" problem in botany, was confronted with the task of measuring the surface area of leaves. He kept postponing the measurements, however, because an expensive planimeter ordered from abroad had not arrived and, according to some textbook, was *the* instrument to use for such measurements. He was amazed that tracing the leaf on to readily avail-when one of us pointed out to him able graph paper with a square millimetre network and then simply counting the squares within the traced figure yields the desired answer with as great (or greater) precision than would have been obtained with the planimeter.

Saving time: In mathematical calculations related to applied scientific or engineering problems, the lack of a conceptual understanding of mathematics often prevents the practitioners from using approximation methods (particularly numerical ones) which yield the answer to the required degree of precision much easier than fancy analytical methods or computer evaluations of the "exact" problem. When in a calculus of variations problem, the shape of a curve has to be optimised, the approximation of the smooth curve by a chain of straight-line segments can reduce the problem to the solution of a simple set of algebraic equations.

The same is true in complicated boundary value problems in differential equations of heat transfer and other problems. Countless hours of precious computer time could be saved on expensive and scarce electronic computers in developing countries if their users were better trained in the fundamental concepts of science and mathematics and relied less on recipies from enginering handbooks or on imitating calculations described in esoteric books dealing with different problems and different tolerance requirements.

Hot water: A solar water heater is to be designed. Even if the basic qualitative principles of such a design are understood, much will depend on the ability to carry out a fairly reliable estimate of heat losses, conversion efficiencies, and the like. For this the scientific principles underlying these phenomena must be clearly understood, because engineering handbooks or the lecture notes saved from university training will hardly give automatic recipes for such "non-standard" situations.

If an engineer claims that he could make steam with such a solar heater, he must also be able to estimate with sufficient accuracy the temperature and the amount of such steam. In the absence of such ability, his project remains an academic exercise and cannot be introduced to "real life" situations where the economic considerations are important and where a quantitative assessment is essential.

A similar situation exists when a claim is made for a design of a practical solar-heat dryer of agricultural products. In this case the useability of the resulting products as well as their quantity will depend crucially on the quantitative factors in the design which, as before, must be estimated on the basis of the scientific principles underlying the engineering applications.

So much for the examples. In seeing them, the reader may advance various objections, at least two of which should be briefly discussed.

The first objection may be that our examples depend not so much on the lack of science but on the lack of "common sense". It is relatively easy to dispose of this objection. Indeed, to a person imbued with some conceptual background in science and technology, the examples may appear a matter of common sense. This is so, however, because he has internalised simple concepts of science and mathematics to such an extent that viewing the world in that light now appears to him a matter of common sense and no longer a matter of science and mathematics.

This is the main point we wish to make: in developing countries such internalisation and fusion of scientific and mathematical conceptual elements with the customary empirical view of the world is very rare, whereas it is much more frequent (though far from universal) in the more advanced countries. This shaping of man's world view is, in fact, one of the primary goals of science in developing countries, and yet it is one that is much too infrequently included in the discussions that prevail throughout "development" literature.

The second objection may be that the missing elements in each of our examples could be provided by a well-trained technologist and engineer and hence science is not really directly involved. In some idealised world this statement may carry some validity. In practice, however, the technological and engineering education, particularly in the developing countries, is such that a functional understanding of the conceptual scientific basis of technology is extremely rare among the graduates of technological and engineering institutions. This is partly so due to directives based on a total misunderstanding of the nature of applied scientific research and of technological development.

According to such directives, engineers and technologists should be given a narrow education in which "unnecessary" abstractions are weeded out and training with respect to a very narrow set of specific projects is the goal. In part, however, the lack of conceptual understanding is due to the lack of contact of these students with teachers who are, themselves, involved in some scientific work and who therefore have had a personal experience with how science is actually done, as distinct from how it appears from the textbooks. Thus we conclude that we need a much greater attention to education.

correspondence

The Natural History Museum needs the best of both worlds

Sir,—The current controversy concerning the Natural History Museum's new exhibition scheme and philosophy, eptiomised in the opposing views expressed by Drs Miles and Halstead (26 October, page 683), highlights problems which certainly deserve the "fullest possible public discussion" as Halstead suggested. While my personal opinion is no more (or less) valuable than that of the next man, as the father of two of the museum's avid users, and also as an ex-curator of one of its scientific sections, I can, at least, see the situation from two different points of view and can make some observations rather more frankly now than when I was still a staff member.

The tremendous gulf between the expressed views suggests that the fundamental question of the museum's role remains to be resolved—despite two centuries of more or less continuous discussion. No-one would dispute the fact that the museum has two distinct general functions, both clearly identified, as Miles points out, by the British Museum Bill of 1753, and as valid today as they were then. The first of these, to carry out research into the natural world, occupies almost two-thirds of the museum's total complement of 750 and sails serenely on with hardly a ripple from the outside world to rock the scientific boat. It is the second, more public role, which attracts all the attention even though it is dealt with on only seven sides of the museum's most recent 170 page report to Parliament.

But while these general functions have remained unaltered, the techniques and approaches needed to discharge them have changed, and will continue to change, throughout the museum's existence. For just as it would be totally inappropriate for the present scientific staff to approach their work in the same manner as their Georgian predecessors, the public galleries should surely bear little resemblance to those of 200 years ago. For one thing, both in numbers and in social stratum, the public served then was very different from that using the museum today. In its early years no more than a few dozen privileged visitors could view the British Museum exhibits each day—and even then only by appointment with a Keeper; as a son of the eighteenth century equivalent of a lorry driver I would personally have had little chance of stepping through the door, let alone of becoming a Curator!

Second, the museum now operates in a different educational environment. The present-day flood of scientific information for the "layman" through books, films, radio and, above all, television did not exist ten, or even one, generations ago. No museum exhibit should attempt to compete with the slickness and immediacy of a television presentation, for whatever you may think of their particular contributions, a Bellamy or a Cousteau can reach a larger and more varied audience in one hour than the BM(NH) could hope to reach in ten years. Surely the museum should adopt a complementary role in these circumstances, concentrating its efforts on those things which it can do better than the mass media by exploiting its particular strengths, its in-house scientific know-how and its vast collections of material.

The official museum view of the way forward seems to be to attempt to put over concepts and ideas to a general public largely devoid of any background in natural history. The opposing "Halsteadian" view, which appears to have the support of a significant proportion of the museum's own scientific staff, seems to favour a return to a more traditional type of "scholarly" display with many examples of the animals, plants and minerals themselves from which the informed visitor can draw his own conclusions. Either approach alone would be dangerous, sterile and damaging to an institution for which so many of us feel the deepest affection. If Dr Miles really believes his survey results which told him that the old displays taught virtually nothing, he should have been with my wife and I when we took our 6-year-old son on his fifth or sixth visit to the museum some years ago. After a depressing appointment with a child psychiatrist had confirmed that he had severe learning difficulties, we were considerably encouraged to have him point out to us the differences between African and Indian elephants in the now dismantled Main Hall exhibit! Like most kids he still likes to see lots of dinosaurs, whales, fishes and so on, and much prefers them to the Hall of Human Biology, which, after its first month, was looking pretty dog-eared by the time we got to it. On the other hand, Dr Halstead's plea for "scholarship" seems equally pathetic. He must realise that not many of us would come up with an evolutionary theory from a perusal of a Cuverian arrangement of specimens, while I cannot imagine what diabolical deeds he envisages the "more inarticulate sections of the community" being incensed to perpetrate as a result of exposure to the Natural History Museum's "social engineering".

However, I feel much more sympathy for Halstead's main worry of a "serious breakdown of communication between the museum's Department of Public Services and the scientific staff . . .". It's all very well to cite the dismay of the museum's "world leading ichthyologist" and "dinosaur expert" at the loss of the exhibits of their respective groups, but they didn't reach their present eminent positions on the strength of their efforts in the exhibition sector. For like the rest of the scientific staff they know that their professional advancement has depended entirely on publication; time devoted to exhibition work has therefore tended to be spent grudgingly and, at least in the past, was often restricted to topping up a dried out bottle or replacing a lost label. Under such circumstances it is little wonder that a them-and-us situation developed between the public and private sections of the staff, with the scientists taking little or no interest in the exhibits for which they were nominally responsible. The scientists can't expect to have their cake and eat it, for if they want a real say in the fate of the exhibitions they must be prepared to be involved. In return, the museum establishment must demonstrate the value they attach to such involvement in terms of career structure and promotions. The Department of Public Services seems to have evolved to fill a gap resulting from the mutual distrust felt on precisely this point.

If there are now two quite distinct, but genuinely held, opinions of the type of exhibitions which the museum should mount in the future, it is surely not too late to exploit the best features of both views. The projected building programme within the museum's existing walls is supposed to provide four times the existing exhibition space over the next three decades. Such an expanse must be capable of housing the traditional scholarly exhibits favoured by Halstead, the exciting new conceptual approach advocated by Miles, and the fun exhibits which the dominant less than 11-year-olds can stare at in wonder and awe and remember in the recesses of their mind for the rest of their lives.

Yours faithfully,

A. L. Rice

New policies are correct

Sir,—There seem to be three separate strands in the recent controversy on the new display policy of the British Museum (Natural History): whether displays should be for scholars or for the general public whether they should be organised by research scientists or by exhibition staff, and whether the former balance of displays should be retained. In each case, I believe that the new policies of the BM(NH) are basically correct.

Until recently, the majority of the displays were little more than a collection of labelled specimens. There was little attempt to point out any features of particular interest, or to help the visitor to appreciate their significance to current scientific theory. Even those displays directed towards university students were suited to a level of knowledge that was not usually attained before the second year of a zoology degree. Similarly, those exhibits that were directed at the reasonably well-informed adult were accompanied by complex and lengthy labels, their comprehension requiring a considerable degree of dedication and time. Finally, many of the exhibits were so old-fashioned as to merit illustration in any book of the history of museum display technique. It can be no surprise that the majority of the visitors to the museum had, as Dr Miles stated "learnt practically nothing". It is surely appropriate that the museum should attempt to inform, as well as interest, the throng of children and of scientifically uneducated adults who nowadays pack its halls.

Should we really expect that the prime responsibility for the new exhibition approach should rest with the scientific staff, already committed to programmes of research and curation? It is no secret that, in any museum, many research workers have little interest in the problems of the design of displays, even if they are of completely conservative and scholarly type. It is even more unlikely that many of them would wish to learn and to apply the theory and techniques of modern displays directed at those with no scientific qualifications. (This is not to say that the scientific staff should have no role in this, and many of those at the BM(NH) certainly seem to feel that they have not had sufficient opportunity to comment on the new policies, or to ensure that the scientific theories illustrated are appropriate and not merely those currently in vogue).

The balance of exhibits is a complex matter. I feel that it is only appropriate that the museum should attempt to let visitors understand themselves as human examples of the world of nature, and to educate them in the basic processes of ecology. (Not even the museum display staff would pretend that every exhibit in the Hall of Human Biology is an unqualified success, but even the BM(NH) must surely be allowed to make the occasional mistake). Furthermore, there can be no doubt that invertebrates and plants have in the past received a totally inadequate proportion of exhibition space. It was therefore inevitable, and only right, that the new exhibits should be at the expense of the great range of extensive (though mainly old-fashioned) displays of living and fossil vertebrates. It is natural for vertebrate zoologists to regret this, but we should surely be reassured by Dr Miles' statement that the new exhibits "will contain the vast majority of the material now on show in the museum".

Yours faithfully,
BARRY COX

Links with school

SIR,—As a teacher of biology, I would like to offer my views about the recent article entitled 'Whither the Natural History Museum?' by Dr B. Halstead.

My earliest recollections of the museum are those of my childhood, when I was taken on the usual tour of the museums on a trip to London. I remember, most of all, the dinosaurs but little else except endless rooms of glass cabinets full of bones and a lot of unpronounceable words.

Today, thankfully, the presentation of material in the museum is progressing and the two most prominent examples of this are the new exhibitions of human biology and ecology. These offer a new and very important dimension to the role of the museum—namely a vital resource which links important aspects of natural science with what is being taught at school.

I have been lucky enough to use the exhibition of human biology as part of my exam course in the fourth and fifth years. The pupils concerned were taught how to use the exhibition and, as a result, were able to benefit from it in a way they could not by just relying on textbooks at school. I look forward to using the ecology exhibition in the same way with my second year groups next summer. The publications accompanying the two exhibitions also allow for follow-up work at school.

From Dr Miles' figures regarding visitors to the museum, it would appear that these exhibitions will benefit an age group whose presence is sadly missing from the museum.

I would like to say in conclusion that the museum should continue to present its rare and fascinating fossil exhibits, as it has done for years, thus fulfilling its role to the scholars; but also to continue with its new fresh approach and present more exhibitions which are of more use to schools and the less scholarly members of the general public.

Yours faithfully,
D. A. WEALE

Teachers need a say

SIR,—I am a teacher in the fourth year of a large multi-cultural East London primary school. I am prompted to write in response to the articles by Dr Miles and Dr Halstead on the future of the British Museum (Natural History).

Dr Miles says that to some extent the Natural History Museum is for children under the age of eleven. He points to the absence of secondary school pupils and university students from the public galleries. Without doubt the primary school children are impressed by the large dinosaurs and blue whales. They take a passing interest in one or two other galleries or individual exhibits but generally scurry through the remainder of the museum if given the opportunity. To the children many of the current displaps seem unrelated to each other or to a wider theme I am not surprised that the majority of younger visitors are not motivated to return for many years.

On the other hand the recent human biology exhibition is stimulating and dynamic and makes demands of the children. In my experience they take an active interest in the displays and are keen to seek answers to questions. Furthermore the exhibition is coherent and so more meaningful to them. Although many of the concepts explained are beyond the grasp of the average eleven year old, I anticipate that a higher proportion are likely to revisit and develop their understanding than would have done had the exhibition remained in the traditional layout. If other recommendations in the paper 'A Proposal for a New Approach to the Visiting Public' are implemented I feel that many teachers and pupils will benefit even more.

It is disquieting to hear of the rift between the Department of Public Services and scientific staff Dr Halstead himself, however, refers to a false dichotomy, by discussing the former dinosaur gallery and its multi-level appeal. Surely the 'new style' exhibition can also be both stimulating and scholarly given the goodwill and collaboration of scientists and exhibition staff. After all Dr Miles does say that the exhibits to be displayed will contain the vast majority of the material on show.

Dr Halstead calls for the fullest possible public discussion. Hopefully teachers at all levels will be given an opportunity to participate in this discussion which at the moment seems to be conducted at the level of the academic.

Yours faithfully,
L. J. STEVENS

Wanstead Park, London, UK

Arborescent animals and other colonoids

SIR,—Comparative biology is sometimes hindered by terms which have become misleading with the advance of knowledge. 'Individual' and 'colony' are such terms when they are used to refer to a single polyp and the entire organism of a reef coral, for instance. The organism responds as a unit in growth and physiology, and it is also the unit of individual selection. I therefore propose two new general terms to replace 'individual' and 'colony' in such cases. Specific terms are already available in some instances, but they vary from taxon to taxon.

Individuoids are parts of an organism which have the general structure of whole free-living individuals but which connect with each other to form a coloniod. A colonoid usually has the same genes throughout and functions as a single individual.

The concept of colonoid grades into that of colony or association, which may be restricted to a group of proximate but physiologically separate individuals, usually of one clone. Intermediate cases might be grass swards or diatom chains. The concept of a colonoid organism also grades into that of individual *sensu stricto*, in which case individuoids may resemble organs. Examples are rooting branches of mangroves, bryozoan avicularise, or cyanophyte heterocysts. Slime mold colonoids are colonoids for only part of the life cycle and may form (sometimes necessarily so) from individuoids of different genotypes. Such fuzzy boundaries of concepts are necessary in the real world.

A diverse array of animals grow in a treelike form. Some but not all have apical meristems. Examples of arborescent growth occur among sponges, hydroids, alcyonarians, corals, bryozoans (including entoprocts[1]), graptolites, pterobranchs, and probably elsewhere. Comparative studies of their growth and that of branched plants and protozoans, from both mechanistic and adaptive viewpoints, have always proved illuminating in my seminar course on the evolution of development and would undoubtedly be more illuminating if pursued more fully.

The study of plants and arborescent animals can thus be mutually beneficial, but such study presupposes that functionally corresponding units are identified beforehand. Studies of other phenomena, such as adaptive strategies, also need clear recognition of what units are appropriate. This has not always been done, perhaps because of the pervasive shadow of a purely morphologically based terminology, and the result is then biological nonsense.

Yours faithfully,
LEIGH VAN VALEN

Biology Department,
University of Chicago, USA

Whaling: past, present and future

from Robert M. May

Few, if any, conservation movements have received as sustained and widespread support as those aimed at 'saving the whales'. Although most of us never have and never will see a great whale outside a museum, we are dismayed by the excessive exploitation these all-time largest of animals have suffered.

People who are vaguely aware of the sorry history whereby stock after stock of whales has been harvested well below the point of maximum sustainable yield (MSY) may be surprised to learn how things stand today. Of the twelve species of whale that have been hunted over the centuries, seven are completely protected in all oceans, three in most ocean areas, and the remaining two in some areas, under the current policies of the International Whaling Commission (IWC). There remain, of course, many problems, not the least being whaling activities under the flags of nations that are not IWC members, and the fact that even for whaling by IWC members the enforcement of agreed regulations leaves a lot to be desired.

The New Management Procedures of the IWC were adopted at its 26th meeting in 1974, and first put into effect in the southern summer of 1975–76 This procedure divides whale stocks in each of the ocean areas defined by the IWC into one of three categories, according to whether the populations are thought to be numerically bigger or smaller than, or near to, the size required to give MSY (for a more full account of the notion of MSY, see *News and Views* **263**, 91; 1976). This classification is revised annually, and more or less automatic rules then applied; if the stock is judged to be below the MSY level, a moratorium is declared ('protection stocks'); if it is near the MSY level, annual quotas are set with the intent of keeping the stock around this level ('sustained management stock'); if the estimated stock size is significantly above the MSY level, exploitation is permitted under quotas aimed to produce a controlled reduction toward the MSY level ('initial management stock'). Application of these rules in 1978 (and in the summer 1977–78 in the southern oceans) produced the numerical quotas shown in the maps. In addition to the wholly protected blue, grey, humpback, and four species of right whales, it will be seen that fin, sei and Bryde's whale are protected in most areas. Sperm whales have significant sexual dimorphism and a more elaborate social structure than the baleen whales, and for them separate quotas are set for males and females (see legend); the models used to obtain these numbers are currently being scrutinised and refined by the IWC.

Before considering the strengths and weaknesses of this management procedure, it is interesting to look at some of the historical background and at the tensions between economic interests and sustainable yield criteria.

History of whaling regulations

The whales that have been hunted include 11 species of baleen whales, which are filter-feeders with baleen plates ('whalebone') in place of teeth: (see box). The largest species of toothed whale, the sperm whale, *Physeter catodon*, is also hunted, and provides most of the present world catch by numbers and by weight (though not by value)

Formerly, these animals provided oil for lamps and lubricants, and the baleen whales also yielded whalebone. Baleen whales remain a source of oil for the manufacture of margarine, soap, and glycerine, of meat which is eaten directly by humans and pets, or used in soups and flavouring and of meat and bone meals for fertilisers and animal foods. Sperm whale oil and spermaceti provide industrial scouring and hardening agents, lubricants and cosmetics. As emphasised by many people, "all these products could be replaced by synthetic derivatives from vegetable and mineral sources, but it is still economically attractive to produce them from whales" (Gambell & Brown *IUCN Bull. Ser. II* **21**, 1; 1971).

Bowhead (Greenland right)	*Balaena mysticetus*
North Atlantic right	*Eubalaena glacials*
North Pacific right	*Eubalaena seiboldii*
Southern right	*Eubalaena australis*
Grey	*Eschrichtius robustus*
Blue	*Balaenoptera musculus*
Fin	*Balaenoptera physalus*
Sei	*Balaenoptera borealis*
Bryde's	*Balaenoptera edeni*
Minke	*Balaenoptera acutorostrata*
Humpback	*Megaptera novaeangliae*

The North Atlantic right whale was hunted by the Basques as early as the twelfth century. By the beginning of the twentieth century, the more easily catchable species—grey, three species of right, bowhead (the latter four species often lumped together as right whales)—were reduced to very low levels of abundance. These are all slow swimmers that usually float when dead, and they were pursued in open boats under oars or sail; real Moby Dick stuff. Whaling for the swifter swimming rorquals—blue, fin, sei, Bryde's and very recently minke—began in the mid-nineteenth century with the invention of the explosive harpoon, harpoon cannon, and the use of steam-powered ships It spread to the Antarctic in 1904, starting at South Georgia. The advent of the factory ship in the mid-1920s freed whalers from land stations, and began the modern era of Antarctic pelagic whaling. By 1935, fears that Antarctic stock would be depleted as Northern ones had earlier been culminated in the formation of an International Convention for the Regulation of Whaling, which banned all harvesting of right whales or of any female whales with calves.

World War II gave the whales a respite. In 1946, the pre-war threads were picked up by a new International Convention which established the IWC, charged to "provide for the conservation, development, and optimum utilisation of the whale resources, [taking]

0028-0836/78/0276—0319$01.00

into consideration the interests of the consumers of whale products and the whaling industry". The grey whale was added to the protected list in 1947.

The Commission is advised by a Scientific Committee, which from early days has issued warnings and pleas that stocks were being exploited too heavily. The present analytical models and quantitative methods of population assessment derive mainly from the work of the Committee of Three Scientists (Allen, Chapman and Holt), appointed by the IWC in 1960. The reports of this committee in the early 1960s made it unanswerably clear that stocks of blue, fin, and humpback whales were being seriously overfished, and in 1963 they recommended total protection of blue and humpback, and a reduction of the Antarctic catch of fin to 5,000 whales or less. The IWC responded by partly protecting the blue and humpback, and reducing the Antarctic catch limit from 15,000 to 10,000 'Blue Whale Units' (this was an atrocious unit, whereby 1 BWU=1 blue, or 2 fin, or 2.5 humpback, or 6 sei) This pattern of the IWC reacting to the advice of its own Scientific Committee by doing too little, too late, persisted. Nonetheless, the 1960s and early 1970s saw some advances as the seeds of the New Management Procedures were sown. the Blue Whale Unit was abolished; two species were added to the list of those completely protected (the blue in the North Atlantic in 1960, the North Pacific in 1966 and world-wide in 1967, and the humpback in the North Atlantic in 1955, southern hemisphere in 1964, and world-wide in 1966): quotas for the Antarctic fin and sei were eventually set under the constraint that they be no more than the estimated sustainable yield.

Outside the IWC, pressures were building up. In 1966, the 1958 Geneva Convention on the Conservation of the Living Resources of the High Seas came into force. adjuring "measures rendering possible the optimum sustainable yield . . . so as to secure a maximum supply of food and other marine products". The UN Conference on the Human Environment, held in Stockholm in 1972, recommended a 10 year moratorium on all commercial whaling. and this recommendation was subsequently adopted by the UN General Assembly and by the General Assembly of the International Union for the Conservation of Nature (IUCN).

The IWC considered this recommendation at its meeting in 1974, but settled for adopting the New Management Procedures described above. The technical details were hammered out in 1975, and led to the following definitions. A protection stock is one which is more than 10% of MSY stock level (MSYL) below the MSY level itself. A sustained management stock is one that is not more than 10% of MSYL below, nor 20% of MSYL above, the MSY level. Finally, an initial management stock is one which is estimated to lie more than 20% of MSYL above MSYL. Thus, for example, if the stock obeyed a logistic recruitment curve, and if the virgin stock density were defined to be 1, then a stock density of less than 0.45 would be protected, between 0.45 and 0.60 would be sustained management, and greater than 0.60 would be initial management The rules also embody some caution with respect to possible errors in the estimates of MSY levels; no more than 90% of the estimated MSY can be taken, regardless of the stock class. Furthermore, for initial management stock, not more than 5% of the estimated initial exploitable stock is to be taken in any one year, unless there is 'positive evidence' that higher levels will not lead to over-exploitation. Nor may significant exploitation begin until a satisfactory estimate of stock size has been obtained. (For more full accounts, see Brown *Polar Record* **18**, 85; 1976; **19**, 59; 1978; *FAO Fisheries Report* No. 194 (the Report of the Advisory Committee on Marine Resources Research, chaired by Laws); 1977.)

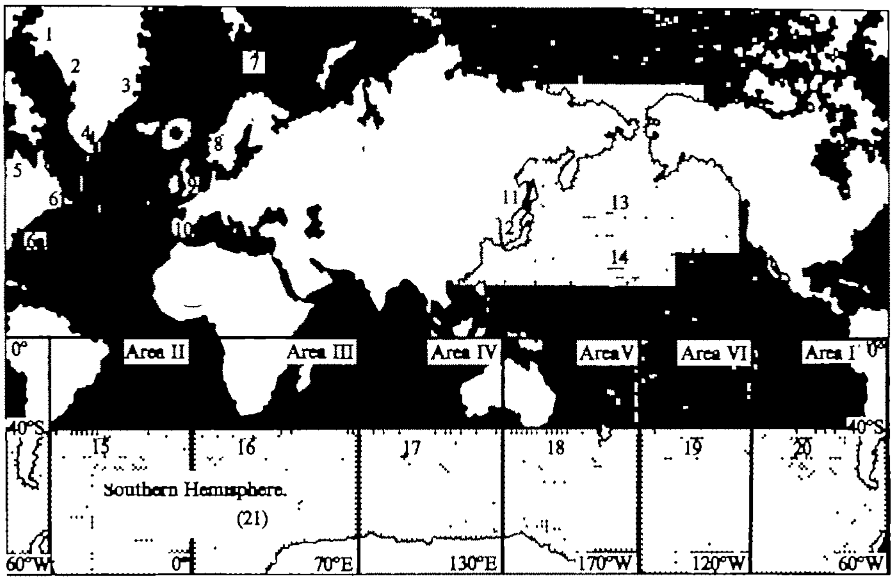

Fig. 1 Quotas for baleen whale species in the various ocean areas designated by the IWC (1977/8 and 1978 seasons). PS stands for protection stock, SMS for sustained management stock, and IMS for initial management stock, as discussed more fully in the text. (1) West Greenland: minke (SMS) 397*, fin (SMS) 4*. (2) Iceland-Denmark Strait: sei (SMS) 84. (3) East Greenland-Iceland: fin (SMS) 304 Not more than 1,524, 1977-1982. (4) East Greenland-Iceland-Jan Mayen: minke (SMS) 320. (5) Canadian East Coast: minke (SMS) 48. (6) Newfoundland-Labrador: fin (IMS) 90. (6a) Nova Scotia: fin (PS) 0; sei (PS) 0. (7) North Norway: fin (SMS) 61*. (8) West Norway-Faroe Islands: fin (PS) 0. (9) Svalbard-Norway-British Isles: minke (SMS) 1,790. (10) Spain-Portugal-British Isles: fin (SMS)*. (11) Okhotsk Sea, West Pacific: minke (SMS) 400. (12) Sea of Japan: minke (SMS) –. (13) North Pacific: fin, sei (PS) 0, Bryde's (IMS) 524. (14) Remainder: minke (IMS) 0 pending a satisfactory estimate of stock size. (15) Sei (PS) 0, minke, (–) 1,150. (16) Sei (PS) 0, minke (–) 1,826. (17) Sei (SMS) 460, minke (–) 963. (18) Sei (PS) 0, minke (–) 930. (19) Sei (PS) 0, minke (–) 688. (20) Sei (SMS) 388, minke (–) 704. (21) fin (PS) 0; Bryde's (IMS) 0 pending a satisfactory estimate of stock size; sei, catch not to exceed a total of 771; minke, catch not to exceed a total of 5,690.

MSY *versus* economic considerations

Reviewing the above history, Gambell and Brown (*op. cit.*) note that "despite warnings from the scientists that the catches were considerably larger than the stocks could withstand in the long term, the whaling nations allowed their industries to take almost as many whales as they could, arguing that they could not otherwise survive economically They leaned on the fact that the scientific evidence was not complete, precise and incontrovertible". The basic reason for this behaviour is that, although the discussions formally centre around sustainable yield (with present and future catches in principle regarded equally), the industry is more interested in economic returns. This tension between MSY principles and economic actualities takes many forms, some of which are widely appreciated and others not; the general issues have been set out incisively by Clark (*Mathematical Bioeconomics*, Wiley, 1976).

The first problem lies in establishing some agency that is effectively the sole owner of the resource. Failing this, an open-access fishery suffers a 'tragedy of the commons' (Hardin *Science* **162**,

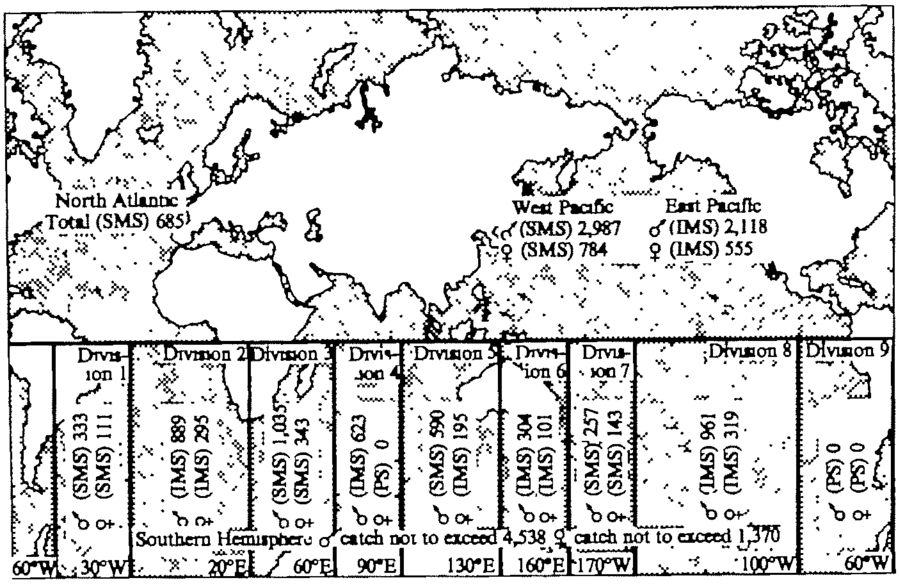

Fig. 2 IWC quotas for sperm whales (1977/78 and 1978 seasons); there are separate quotas for males and females.

1243; 1968), in which the 'economic rent' is dissipated by exploitation down to the point where revenues are balanced by harvesting costs. The establishment of the IWC, which aims to act as such a sole owner, is thus a non-trivial accomplishment for which its members deserve credit. It is in the nature of the situation that there remains a tendency for individual ships (and even—whisper it—nations) to cheat.

Moreover, as stressed by Clark (see also *News and Views op. cit.*), whalers are interested not in maximising sustainable biological yields, but in maximising the present value (PV) of net economic return, discounting the future. If the economic discount rate is small compared with the biological growth rate of the exploited stock, these considerations are relatively unimportant, and MSY and PV criteria lie close. But if the economic discount rate is greater than, or of the order of, the population's intrinsic growth rate (as arguably is the case for whales, where growth rates lie around 5 to 10% per annum), the PV criterion will tend to lead to stocks being depleted below the MSY level. Indeed in the limit when the discount rate becomes infinite (which in practice means when it significantly exceeds the biological growth rate) exploitation by a sole owner is mathematically identical with the open-access case. The reason is intuitively clear; with relatively high discount rates there is, just as in open-access exploitation, no motive to heed the future These remarks are subject to many qualifications, among them that prices, harvesting costs, and inflation-corrected discount rates are all liable to change over time (Clark, *op. cit.;* Gulland, *Nature* **263**, 722; 1976; Clark & Munro *J. Env. Econ. Mgmt.* **5**, 198; 1978). All this can make for great complications in the analysis, but I think the essentials are as above.

These economic considerations have some subtle corollaries which are not so widely acknowledged. Clark and Munro (*J. Env. Econ. Mgmt.* **2**, 92; 1975), for example, have shown that the optimum trajectory for capital investment can, under some circumstances, lead to an initial rapid phase of heavy exploitation, possibly even depressing stock below the level that maximises PV (much less SY), followed by a slower phase in which the stock levels recover to and are maintained around the PV level. Very crudely speaking, these two phases correspond to fast capitalisation followed by relatively slow amortisation of the equipment.

Even within an agreed MSY framework, there is room for squabbles motivated by economics. One such dispute at present concerns whether the quotas for sperm whales should be set for MSY by numbers or by weight. It happens that for sperm whales a significant fraction of the life-long growth in size takes place during the exploited adult phase of the life cycle. The result is that, once the equilibrium age structure is attained under a given harvesting regime, MSY by weight gives a total catch greater in biomass (and thus in products) and lower in numbers (therefore requiring less effort and lower harvesting costs) than is obtained by MSY based on numbers (Holt, FAO Document ACMRR/MM/SC/99; 1976). Unambiguously, the long term advantage lies with MSY by weight. The snag is that several years must elapse before sperm whale populations change from the existing age structure, produced by harvesting for MSY by numbers, to that appropriate to the MSY weight criterion. If the future is heavily discounted, one will always argue for the numbers criterion, because this will allow more whales to be caught, and, in the immediate future, their average weights will be much the same under either quota system. In this way can the future be squandered even in an MSY context.

One bleak consolation lurking in the above discussion is the possibility that whaling, once it is effectively controlled at MSY (as opposed to maximum PV) levels, may cease to be economically attractive. This issue, however, requires taking a longer view of prices and costs than I am prepared to do.

Prospects for the whales

The present biomass of large whales is estimated to be about 23 million tons, which is about one-third the value around 1900 (FAO *op. cit.*). Some species have, of course, suffered very heavily; for example, the populations of blue and humpback are down to a few percent of their pristine numbers. However, no species has been extinguished by whaling, although the grey whale is extinct in the North Atlantic.

Ironically, the one species that could conceivably be in danger of extinction is the bowhead. Although this species has long had protection status, up to 1978 the IWC rules permitted hunting by aboriginal peoples. Recent increases in the prosperity of societies of Alaskan Eskimos have resulted in their hunting with more boats, which seem on the average to be less ably manned. Not only have the number of bowhead caught increased markedly over the past decade (from an average around 9 per annum in 1912-1967 to around 27 over the past decade: Chapman, *Marine Mammal Information*, Dec 1977), but the number struck and lost has greatly increased. It is likely, although in dispute, that the number of animals thus killed exceeds the number actually harvested. Conservative estimates suggest the present levels of exploitation exceed the rate of net reproduction. The sentimental argument that these people should be allowed to continue their depredations, lest their traditional culture be imperilled, seems to me to miss the point that the current problems arise largely because the traditional culture is already collapsing.

The only stock that has demonstrably recovered under protection is the grey whale in the eastern North Pacific (the California grey whale). Some humpback and some right whale populations show indications of increases in recent years. It is still too early to detect with assurance whether blue whale stocks have been increasing since they were protected. The uncertainties here derive from the difficulties in getting enough survey data to measure significant changes in abundance.

The New Management Procedures have the virtues of recognising individual species and geographical stock units, each subject to its own management regime, and of classifying stock with the explicit aim of long term conservation. The allowance for a margin of error in the estimation of MSY level is another step in the right direction; this precaution helps offset uncertainties in the determination of population parameters, and gives some buffering against the unpredictable environmental fluctuations to which all natural populations are subject to one degree or another. The procedures thus go some way toward meeting the broad principles for conservation and management articulated in the so-called Airlie proposals, which emerged from a consultation sponsored by the World Wildlife Fund, the Ecological Society of America, the IUCN and others (see Holt & Talbot *Wildlife Monogr.* No. 59; 1978).

The New Management Procedures could be improved in at least three ways. First, they could explicitly acknowledge the long time lags inherent in the dynamics of whale populations, and the problems these cause. Second, they should aim to maximise the net sustainable yield of whale products rather than the number of whales caught; that is, they should take full account of whaling costs, and should maximise the catch by weight not by numbers. Finally, and most difficult, it needs to be recognised that whale stocks are not single species, but are constituents of a multispecies ecosystem. A management procedure that (as required by the US Marine Mammal Protection Act of 1972) takes due account of the 'health and stability of the ecosystem' will need to grapple both with technical issues of multispecies MSY criteria, and with broad ecological questions of the possible existence of alternative stable states.

Immunoglobin genes: more facts to guide speculation

from W. A. Dunnick

BIOLOGISTS have proposed all sorts of genetic gymnastics for immunoglobulin genes. They have suggested that immunoglobulin genes hop around chromosomes, and recombine or mutate at terrifying rates. The genes have been amplified, branched, interrupted by episomes, and somatically diversified, but never understood. Immunoglobulin genes attract this bizarre speculation because of the protein's enigmatic structure.

Both the light and heavy chains found in immunoglobulin proteins have structurally simple carboxtermini. For example, the carboxy halves (C-regions) of about 95% of mouse light chains have an identical 'kappa' sequence. The remaining 5% are divided between two related 'lambda' sequences. On the other hand, the amino terminus (V-region) is very heterogeneous in sequence. Individual mice may be able to express 10,000 different V-regions. The variability is not random, but is concentrated in three 'hypervariable' regions. No other group of polypeptide sequences implies such an extensive, yet nonrandom, divergence of genes. Most speculation concerning immunoglobulin genes centres on two problems: (i) the bringing together of the very different V and C sequences to form a single polypeptide, and (ii) the generation of V-region diversity.

V–C joining

If each of the 10,000 V-genes were associated with a C-gene, the first problem would be solved. However genetic and gene counting experiments have shown not thousands, but only a few C-genes. Thus, this simple model must be excluded.

A second simple model would be the association of a few C-genes with a few V-genes. Mutations in the V-genes during somatic development could give rise to 10,000 different V sequences (in 10,000 different cells) associated with a single C sequence. However, there seem to be more than a few germline V-genes. V-regions are grouped according to shared amino acid sequences; members of a single subgroup share three or more residues not found in other subgroups. To avoid the unpalatable assumption of parallel mutation, each subgroup is thought to be coded by at least one germline gene. Such an analysis implies that the few kappa C-genes must accommodate 50 or more kappa V-genes.

Dreyer and Bennet (*Proc. natn. Acad. Sci. U.S.A.* **54**, 864; 1965) proposed that V and C-genes are brought together by a translocation event, cells expressing different V-regions rearranging different V-genes. Hozumi and Tonegawa (*Proc. natn. Acad. Sci. U.S.A.* **73**, 3628; 1976) demonstrated such a rearrangement for a mouse kappa chain (see *News and Views* **264**, 699; 1976), and rearrangement of V and C-genes has also been shown for a second kappa chain (Rabbitts & Forster *Cell* **13**, 319; 1978) and for a lambda chain (Tonegawa *et al. Cold Spring Harbor Symp. quant. Biol.* **41** 877; 1976).

These observations suggested that translocation results in the contiguous V–C sequence found in mRNA (Milstein *et al. Nature* **252**, 354; 1974). It was soon demonstrated that this is not the case. Nucleic acid hybrids between kappa cDNA (Rabbitts & Forster, *op. cit.*) or mRNA (Matthyssens & Tonegawa *Nature* **273**, 763; 1978) and their respective myeloma genes have looped-out, single-stranded regions that are susceptible to S1 nuclease. The size of the products of S1 digestion suggests that the discontinuity in the gene is near the V–C junction. Also, electron microscopy of R-loops formed between lambda mRNA and a cloned myeloma V+C gene reveal a 1,200 base pair intervening sequence between the V and C coding sequences (Brack & Tonegawa *Proc. natn. Acad. Sci. U.S.A.* **74**, 5652; 1977).

The complete structure of the mouse lambda germline gene (Bernard, Hozumi & Tonegawa *Cell*, in the press) has now been determined. It consists of 45 bp coding for the lambda signal peptide, 306 bp of variable region, more than 4,500 bp of undefined DNA, 39 bp of variable region sequence, approximately 1,200 bp of intervening sequence, 312 bp of constant region sequence. (The preceding implies that the V-gene is 'upstream' relative to the C-gene; this is not known to be the case.) In cells producing lambda light chains, a translocation event fuses the two V segments, eliminating the large undefined segment of DNA from the active gene. The small segment of 'variable' region associated with the C-gene (albeit 1,200 bp away) is a surprise. Bernard *et al.* have termed the segment J, emphasising its role in V–C joining. J. Seidman and colleagues (NIH) reported a similar structure for a kappa gene at the Seventh Workshop on Homogenous Antibodies*.

We are left with the V and C-genes over 1,000 bp apart in myeloma DNA,

but contiguous in mRNA. Three lines of evidence indicate that nuclear RNA precursors (Gilmore-Hebert & Wall *Proc. natn. Acad. Sci. U.S.A.* **75**, 342; 1978; see also Schibler, Marcu & Perry *Cell* in the press) contain these intervening sequences. First, hybrids between cDNA and the precursor RNA are not perfect matches, but have single-stranded regions near the V–C junction (Rabbitts *Nature* **275**, 291; 1978). Second, the precursor and mRNA apparently have the same nucleotide sequence in the C-region. On the 5′ side of the C-region, sequences in the precursor differ from those in the mRNA (Rabbitts *op. cit.*). Third, ultraviolet inactivation experiments suggest that V and C coding sequences are not adjacent in nuclear RNA (R. Wall & M. Gilmore-Hebert, University of California, Los Angeles, reported at Homogenous Antibodies Workshop). The intervening sequences in nuclear RNA must be removed by some RNA processing mechanism.

Single cells produce only one sort of light chain, but seem to be able to couple one heavy chain V-region with two or more heavy chain C-regions (for example, mu and gamma C-regions). Several authors have suggested that the heavy chain V-region may be cotranscribed with several C-regions, and that RNA processing would determine which heavy chain V–C combination(s) is to be expressed. This elegantly simple idea will have to be revised; hybrid cells producing two different classes of heavy chain do not exchange V and C-regions (Milstein *et al. Cold Spring Harbor Symp. quant. Biol.* **41**, 793; 1977; Köhler & Schulman *Nature* **274**, 917; 1978). For example, hypothetical 'mu' processing enzymes do not bring together the mu constant region and a variable region associated with a gamma constant region, even though both genes are transcribed in the same hybrid cell. In addition, R. Perry, U. Schibler and K. Marcu (Institute for Cancer Research, Philadelphia) reported at the Homogenous Antibodies Workshop that both gamma and alpha heavy chain mRNAs are transcribed as precursors at least 8 to 11 kb long. Nevertheless, neither mu nor alpha transcripts are detected in the nucleus of the gamma producer, and neither mu nor gamma transcripts are found in the nucleus of the alpha producer. Thus, the mu-gamma-alpha switch cannot be explained by a simple RNA processing model (for an alternative theory, see Honjo & Kataoka, *Proc. natn. Acad. Sci. U.S.A.* **75**, 2140; 1978).

V-region diversity

The extraordinary results discussed above have solved, in a general way, many of the problems of light chain V–C joining. In relation to V-region diversity, many immunologists believe that some number of germline V-genes (say 100 to 1,000) diversify somatically to yield a larger number of total genes (10,000). However, this is not to say that all immunologists endorse such a statement; the gap between belief and proof has been great. Kinetics of hybridisation experiments have suggested a limited number of germline V-genes, but the interpretation of such data is very difficult (see Smith *Cold Spring Harbor Symp. quant. Biol.* **41**, 863; 1977; Rabbitts & Milstein *Cont. Topics Molec. Immun.* **6**, 117; 1977).

The extensive study of one kappa group (V21) has been more informative than investigations of the widely diverse kappa chains as a whole, or studies of kappa groups in which only a few amino acid sequences are known. The V21 group may be divided into at least six subgroups on the basis of related sequence patterns (McKean *et al. Proc. natn. Acad Sci. U.S.A.* **75**, 3913; 1978; Weigert *et al. Nature*, in the press). The subgroup structure is most clear if residues 99–110 (J-region) of the V-regions are ignored. The V21 subgroups seem to randomly associate with eight J-regions (Weigert *et al. op. cit.*) As Bernard *et al.* (*op. cit.*) proposed, V-region diversity may increase through recombination of V and J-regions or through imperfect V-J joining. Using a hybridisation technique (saturation) which should be more accurate than kinetic measurements, Valbuenna *et al.* (*Nature*, in press) have suggested that the number of V21 germline genes is the same as the number of subgroups (four to six). This would strongly favour somatic variation in this group, since nearly 30 amino acid sequences have been determined. Impurities in the cDNA preparation complicate the interpretation of these results, and one eagerly awaits the results of such experiments with cloned cDNAs

Seidman *et al.* (*Science* **202**, 11; 1978) have also suggested that mouse kappa V-genes are represented in the germline by groups of at least six closely related genes. Two-dimensional 'fingerprints' of mouse DNA reveal six to ten bands of hybridisation to each of two different cloned kappa probes. Even though the two probes identify the same C-region band, they have no V bands in common. The authors speculate that the total number of kappa germline V-genes is 200 to 1,000. Experiments with many light chain probes will be necessary to reach a more precise estimate.

Cloning and sequencing of two V-genes hybridising to the MOPC 149 kappa probe have demonstrated that the two genes vary from each other and from the MOPC 149 V-gene by about 7%. The two V-genes are also homologous over 2,500 bp of flanking sequence. Seidman *et al.* expand an earlier hypothesis of Edelman and Gally (*Proc. natn. Acad. Sci. U.S.A.* **57**, 353; 1967). V-region diversity is expanded by recombination, the recombination being facilitated by the homology between flanking regions of different V-genes. The hypothesis is especially persuasive, since other structural genes (β-globins) diverge more slowly, and have less flanking region homology.

In spite of the abundance of remarkable data, our concepts of immunoglobulin genes remain vague in several areas. Are any special mutational mechanisms required to generate V diversity? How are heavy chain genes rearranged and joined? What is the molecular basis of immunological memory and tolerance? And finally, cellular immunologists spend more time with T cells than with immunoglobulin-producing cells these days. How do T-cell receptor genes relate to Ig genes. ☐

Cosmic spherules

from D. W. Parkin

MOST scientists will not have heard of cosmic spherules, yet Murray and Renard found and named them long ago (*"Challenger" Reports* **4**, 1891). About a dozen of these extraterrestrial spherules, ~ 100 μm diameter, can be magnetically extracted from a cupful of deep oceanic red-clay, which slowly deposits at a few metres per 10^6 years They are black and quite spherical. Two types occur: the 'stones' and the 'irons', although a few might be called 'stony-irons'. The stones are olivine $(Mg, Fe)_2SiO_4$ and magnetic Fe_3O_4; a little glass may be present but not as a noticeable phase. The irons are magnetite and wüstite FeO; often a globule of Fe/Ni alloy is present, eccentrically placed in the oxide shell. There are other rounded magnetite forms in the red-clay which are not extraterrestrial. These occur especially in the less than 30 μm-sized range Probably these faceted and very shiny black forms are growths on the sea bed or may come from volcanoes. Care is needed not to confuse these small particles with cosmic spherules. Above 50 μm there is little chance of contaminating a collection. The fact that the ratio of stones to irons is the same in any surface sample of red-clay provides a strong argument for an extraterrestrial source for both types of spherules.

Most meteorite experts would accept the extraterrestrial origin; but they

0028-0836/78/0276—0323$01.00

have tended to ignore cosmic spherules, believing that they are merely droplets sprayed from a meteorite as it ablates in the atmosphere. On the other hand, Opik (*Irish Astr. Jour.* **1**, 145; 1951; **4**, 84; 1956) proposed a more interesting origin: cosmic spherules are formed in the atmosphere by the melting of similarly sized fragments coming directly from the zodiacal cloud. Using his micrometeorite formula, he was able to predict size-distributions for cosmic spherules. Unfortunately, when the predicted and observed distributions are compared, the fit is not exact. Most zodiacal cloud particles are known to orbit the Sun with low inclination to the plane of the ecliptic, but it is not known how many of them depart from circular orbits. Therefore, there is some flexibility in the allowed velocity of impact with the Earth's upper atmosphere; also the shape of the impacting fragment enters into the theory. With contrived and somewhat artificial mixtures of velocities and/or shapes, a better fit can be achieved. Hunter and Parkin (*Proc. Roy. Soc.* **A255**, 382; 1960) largely avoided these complications by comparing the size distributions of stones with irons and they considered that Opik's zodiacal hypothesis was essentially correct, but the argument was not convincing. Meanwhile, to prove a zodiacal origin, interest was centred on making day by day airborne collections of cosmic spherules at remote sites; but these promising activities soon died away. The collections were always contaminated by industrial magnetic spherules. During the 1960s no positive progress favouring the zodiacal origin could be made; the rather uninteresting meteoritic ablation mode of formation was the only idea that prevailed.

Now, as a result of a few recent papers, interest in cosmic spherules is likely to be renewed. Brownlee *et al.* (*Interplanetary Dust and Zodiacal Light*, Eds. H. Elsässer and H. Fechtig, Springer-Verlag, 279, 1976) have painstakingly identified extraterrestrial dust by using aircraft in the stratosphere. Amongst these μm-sized crumbs, most of which are like carbonaceous meteoritic material, similar sized spherules have been found at about 10% frequency. It could be that both crumbs and spherules are coming directly from the zodiacal cloud. Parkin *et al.* (*Nature* **266**, 515; 1977), using scanning electron microscopy and X-ray diffraction on cosmic spherules, were persuaded that spherules are not meteoritic ablation droplets. From their surface texture, which shows only slight but varying atmospheric damage, it was claimed that cosmic spherules are already round bodies in space. With these ideas of non-molten (grazing) atmospheric flight, Opik's theory can be used to give a much more convincing explanation of the size-distributions, stones and irons being treated separately. If a spherule (on a plunging flight) was heated to melting temperatures, the size distribution analysis predicts that it would be destroyed; probably due to evolution of solar-wind gases accumulated during the spherule's residence in space. Very recently, Ganapathy *et al.* (*Science* **201**, 119; 1978) have analysed three stony spherules for trace elements, using neutron activation techniques. Not only do these analyses remove any lingering doubts about the extraterrestrial nature of stony spherules, but they break new ground in the chemical classification of cosmic spherules. This will become especially evident when more are analysed.

Of the eight elements analysed (Ir, Ru, Sc, Fe, Co, Ni, Cr, and Au) the amounts of Ir, Ru, Ni and Cr differ widely across the three spherules. Extra elements Zn, Sr, Os, Sb, Cs, Ag and Se are given for the third spherule. The authors also mention that S is highly depleted in these and other spherules. When the third spherule is compared with carbonaceous meteorite (C1) agreement is good, except for Au, Cs, Zn, and Ag which show moderate depletion. High depletion of very volatile Se and S is readily understood: the spherules have been molten at some time in their history. It is tempting (as the authors do) to compare cosmic spherules with C1 meteorites; and to attempt to derive each spherule from some primitive and homogeneous material, explaining the depletions and differences on the grounds of volatilisation on melting and leaching on residence in the sea water. But there is no compelling reason to do this for every spherule. It might turn out, when more spherules are analysed, that distinct families appear; with each family relating to the different meteorite types. It could even be that cosmic spherules are sparks from colliding meteorites or asteroids, the detailed chemical differences amongst them reflecting differences in the colliding bodies. Volatilisation of the moderately volatile elements or leaching of the soluble elements may not be as serious as Ganapathy *et al.* suspect—Cs is not highly depleted. In fact, we believe that most stony spherules in the surface sediments have not been severely attacked by sea water; the pores between the crystal grains being a natural freezing feature.

However, whatever the outcome of all this recent work, cosmic spherules are likely to become more widely talked about in future years. A pressing need is to find out where in the Solar System they are being created. This may be possible by examining deep-sea cores and using the fact that radiation from the Sun causes a drag on the orbiting spherule, the so-called Poynting–Robertson effect. Initial results from a red-clay core from the Pacific suggest the asteroidal belt. □

Muon spin rotation

from G. C. Stirling

ONE test of the public recognition of a new scientific technique is its emergence in the chemical sciences: optical spectroscopy, magnetic resonance spectroscopy and Mössbauer spectroscopy are common examples which have crossed the frontier from research curiosities in physics to routine tools in chemistry. The latest candidate is notable in representing spin-off from particle physics, a frequently-invoked, if trivial, justification for the vast funding accorded high energy physics research in recent years.

μSR—the acronym stands for Muon Spin Rotation, Relaxation, Resonance, Research or what have you, and refers to the analogy with NMR and ESR—has now come of age in this way after a relatively short adolescence, and at the recently-held first international meeting* on the subject much of the most promising new work related to purely chemical problems Indeed, the use of muons in chemistry is striking not only for providing yet another probe of chemical systems, but for opening up an entirely new field of study—muonium chemistry—with important implications for related disciplines.

The μSR method in itself is conceptually simple, and derives from various serendipitous properties of the muon: it has a mass about 200 times that of the electron, a lifetime of 2.2 μs, and muon beams are inherently spin-polarised. Muons are rapidly stopped in bulk matter, and the spin direction is maintained during the thermalisation process. Subsequent interaction with local internal fields or with externally applied fields causes the muon spin to undergo a Larmor precession, and it is the precise behaviour of this precession which provides detailed information on the local muon environment. The precession is readily observed by the spontaneous muon

---

*First International Topical Meeting on Muon Spin Rotation, held at Rorschach, Switzerland, 4–7 September 1978.

0028-0836/78/0276—0324$01.00

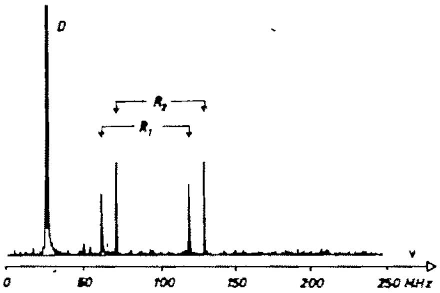

Fig. 1 Muon procession frequencies derived from the measured μSR time-histogram for 2-methyl-1,3-butadiene, with an external field of 1 kG. R_1 and R_2 originate from muonium-substituted radicals (after Roduner *et al., Chem. Phys. Lett.* **57**, 37; 1978).

decay, which leads preferentially to positron emission along the instantaneous muon spin direction, and appropriately located positron detectors give a direct observation of the time evolution of the muon polarisation

Chemically the most interesting possibility is the formation and subsequent behaviour of the atomic species muonium ($\mathrm{Mu} \equiv \mu^+ e^-$) Muonium has a similar size and ionisation potential to the hydrogen atom, and a mass some nine times less It therefore would be expected to behave like a superlight hydrogen isotope, providing possibilities for observing dramatic H/Mu isotope effects in chemical reaction kinetic studies (compared with the relatively staid hydrogen-deuterium difference) Indeed, measurements of rate constants for the reaction $\mathrm{Mu}+\mathrm{Br}_2$ is the gas phase (Fleming *et al., J. Chem. Phys.* **64**, 1281; 1976), and Mu in aqueous solutions (Percival *et al., Chem. Phys. Lett.* **47**, 11; 1977; Jean *et al*, *Chem. Phys Lett.* **57**, 293; 1978) have demonstrated the chemical similarity of H and Mu, although a detailed interpretation of observed isotope effects has been frustrated by the realisation that much of the previously accepted H atom data must now be reassessed. A new development reported at the Rorschach meeting concerns the direct observation of muonium-substituted radicals in solution Although measurement of muonium rate constants obviously may imply the formation of such radicals, it is only recently that they have been observed directly in a μSR experiment (Roduner *et al., Chem. Phys. Lett.* **57**, 37; 1978) In muonium-substituted radicals the observed frequency spectrum is dependent on the coupling of the muon spin with those of nearby nuclei and unpaired electrons, leading to characteristic spectra. A typical example is shown in Fig. 1, corresponding to radicals $\mathrm{CH_2{=}C(CH_3)CHCH_2Mu}$ and $\mathrm{CH_2MuC(CH_3)CH{=}CH_2}$. Hyperfine coupling parameters are derived from the spectra, and the large isotope effects compared with the analogous hydrogenous radicals are related to equilibrium structure and vibrational and rotational motions of the radical species. The implications of this work for reaction rate theory and radiation chemistry are substantial, the importance of the μSR technique lying in its unique sensitivity—since only one muon may be in the sample at any one time, reactions are pseudo-first order, and the reacting muonium species can in principle be identified unambiguously from its depolarisation behaviour

Why then, this apparently sudden activity in condensed matter applications of the muon? The answer undoubtedly lies in the availability of high quality muon beams at the new meson factories in North America, the USSR and Western Europe (though not, one notes, in the UK, although the proton synchrotron of the so-called spallation neutron source at the Rutherford Laboratory may yet provide a world ranking source). A striking feature of these facilities is the overall tendency towards 'applied' research, most markedly demonstrated by the Muon Spin Rotation technique itself. At the recent meeting for example, investigations using μSR included, in addition to purely chemical work, studies of the electronic structure of impurities in metals and magnetic materials, the behaviour of μ^+ and muonium in insulators and semiconductors, and the study of defects in radiation-damaged materials. As usual the biochemists have been quick to assess the potential of the technique in their own work. The proceedings are to be published in a volume of *Hyperfine Interactions* early in the new year, and this will doubtless serve to acquaint a larger audience with the possibilities of the technique for the first time Already preliminary plans are in hand for a second international meeting, most probably to be held in Vancouver in 1980 ☐

G. C. Stirling is at the Rutherford Laboratory of the Science Research Council.

Superfluid ^{3}He in narrow cylinders

from Dieter Vollhardt

SUPERFLUID ^{3}He is a fascinating liquid—it has an unusually large number of internal degrees of freedom, it is inherently anisotropic and displays uncommon magnetic properties There exist three superfluid phases. A, A_1 and a B phase which all differ in their spin-configurations. The A phase, in particular, can be characterised by two unit vectors: (1) the vector **l**, which describes the angular momentum of a ^{3}He–^{3}He Cooper pair and which is the anisotropy axis affecting, for example, flow motion of the liquid, and (2) the vector **d**, describing the spin part of the underlying wavefunction (if S is the total spin of a Cooper pair then $\mathbf{d}{\cdot}S$ is a constant of motion).

Both vectors are thus internally defined directions, which characterise the degrees of freedom of the superfluid and which will form vector fields defined throughout the whole sample Given a container and external fields, **l** and **d** will form a configuration such as to minimise the energy of the system. For this to occur several conditions, which usually all compete with each other, have to be optimised: (1) **l** must be perpendicular to any wall, (2) **d** and **l** want to be as straight as possible because bending costs energy; (3) **d** wants to be perpendicular to an external magnetic field because of the susceptibility anisotropy and finally **l** and **d** want to be parallel due to the nuclear dipole interaction in a ^{3}He–^{3}He pair. It is this very energy that leads to the unusual magnetic properties of superfluid ^{3}He, which become particularly evident in nuclear magnetic resonance (NMR) experiments. The bulk A phase hence shows not only a transverse resonance frequency which is strongly shifted away from the Larmor frequency but also a longitudinal resonance! By means of NMR experiments one can then indirectly obtain information about the **l** and **d** configuration in a sample, because **d** will oscillate in the potential provided by the **l**-vector, giving rise to particular resonances Of all textures the coupled **l** and **d** fields can build up, those which are non-uniform and show textural defects and singularities are of particular interest Quite generally the topics of defects and singularities in condensed matter physics and their classification has been of great theoretical interest for the past 2 years (see, for example, Toulouze & Kleman, *J Phys. Lett.* (*Paris*) **37**, L-149; 1976).

While some experimental work on non-uniform textures (without singularities) has been done already the first experimental studies which specifically deal with singular textures have only recently been reported (Saunders *et al. Phys. Rev. Lett.* **40**, 1278; 1978; Gould & Lee, *Phys. Rev Lett.* **41**, 967; 1978).

Dieter Vollhardt is at the Department of Physics, University of Southern California, Los Angeles

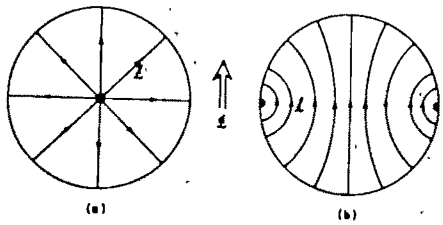

Fig. 1 Two possible planar textures of the **l** vector confined in a long cylinder *a*, Modified de Gennes disgyration with the **l** vector strictly radial, giving a singularity in the centre, and the **d** vector uniform. *b*, The 'Pan-Am' texture with two singularities on the walls. **d** is again uniform (from Gould and Lee, *op. cit.*).

By a rare coincidence both groups carried out NMR measurements of A-phase textures in the same type of very narrow cylinders (2 μm diameter). In the experiments an external static magnetic field was applied parallel to the cylinder axes with rf fields parallel and transverse to this to measure the longitudinal and transverse resonances. In addition, Gould and Lee also reported measurements of a transverse resonance with the external magnetic field perpendicular to the cylinders. The confinement of the superfluid in these narrow cylinders has drastic consequences for possible **d** and **l** textures. As bending of **l** and **d** usually takes place over a distance of typically 10 μm, such a deformation will cost quite a lot of energy if it happens over a length of 2 μm, even more energy than to have a singularity somewhere in the plane of the cylinder. The only known non-singular texture that would fit into a cylinder, the so-called Mermin-Ho vortex, can be shown to require too much bending energy to be a favourable candidate, so that the only possible textures must bear singularities. With a magnetic field parallel to the cylinder one would thus *a priori* expect planar textures with **d** uniform across the sample (in the plane of the cylinder cross section) and the **l**-field looking somewhat as in Fig. 1.

Measuring the transverse NMR signal, both groups find two resonances where initially most of the weight lies in the higher frequency mode; however, this mode slowly decays into the lower mode over 40–60 min, which seems to imply a textural transition. The two groups measured somewhat different NMR frequencies and while the resonances of Gould and Lee proved to be temperature dependent (suggesting a temperature-dependent texture) the one of Saunders *et al.* did not depend on temperature Their results for the longitudinal resonances are also different. Gould and Lee find a single, well defined, longitudinal resonance (temperature dependent) which does not change during the textural transition, while Saunders *et al.* do not observe any such resonance, which would be consistent with an axially symmetric texture. Whether the differences in the results can be explained by the different experimental setups (Gould and Lee for example, use Pomeranchuk cooling, Saunders *et al.* use nuclear demagnetisation) is unclear. The results, however, lead to the following conclusion. in both experiments the first texture seems to decay into a similar one, whose projection into the plane of the cylinder's cross section is about the same (so they give the same longitudinal resonance) The initial textures that would be fairly consistent with the NMR-resonances are the de Gennes disgyration in the case of Saunders *et al.* and a somewhat distorted 'Pan-Am' texture (Bruinsma & Maki, private communication) in the case of Gould and Lee The deviations of the cylinder cross sections from a circular shape—they have a rounded hexagonal structure as can be seen on magnifications—probably need to be considered The only alternative mechanism that could, at least qualitatively, account for a distortion of textures in the direction of the cylinder axes in both experiments and the temperature dependence in Gould and Lee's results seem to be superfluid currents in the cylinders.

To explain quantitatively what textures are responsible for the measured NMR resonances will not be an easy but most certainly a very rewarding task. It will provide us with new understanding of textures and singularities in superfluid ^{3}He, and beyond that in condensed matter systems. □

Germs from Mars?

from Arie J. Zuckerman

THE health and environmental hazards of bringing to Earth surface soil samples from Mars, assuming that life exists on that planet, have been discussed for over a decade. On the one hand, views have been expressed that the risk of the spread of virulent Martian organisms to terrestrial life forms is so great that such an undertaking planned for the 1980s should be abandoned (see, for example Young & De Vincenzi *Science* **186**, 496, 1974) In a recent cogent discussion of the problem (*COSPAR: Life Sciences and Space Research* XVI (eds Holmquist & Strickland) Pergamon, 1978) Martin Favero points out that adequate containment facilities for microorganisms are now available, although absolute security in a scientific sense is of course impossible to guarantee It is therefore necessary to examine the risks in terms of possibilities.

Favero develops his argument for the unlikelihood of Martian microorganisms' causing harm as follows. If life exists on Mars such organisms would be adapted to low temperature fluctuations and virtually no oxygen or water in the atmosphere. It could reasonably be assumed that such organisms will be so adversely affected by the Earth's environment that Herculean scientific efforts will be required simply to maintain them. Counter arguments could be that terrestrial microorganisms survive under wide ranges of conditions, which is in principle true, and furthermore Martian organisms might remain unrecognised by the host's immune and other defence mechanisms thereby resulting in devastating infections. However, in general terms, microorganisms that have no association with man are not pathogenic, for example hydrogen bacteria, methane bacteria and blue-green algae. Another argument is that extraterrestrial microorganisms might be resistant to inactivation, for instance to heat. It is pointed out that heat which destroys carbon bonds will destroy Martian organisms If they survived, it would be because their biology was not based on carbon, in which case they should not be pathogenic for forms of life whose biology is based on a carbon system. Finally, there is the potential risk of exchange of genetic material between Martian organisms and terrestrial forms of life. However, there is no evidence of efficient transfer in nature of genetic material between heterogeneous broad groups such as bacteria, algae, fungi, protozoa, higer plants and animals, and the probability of introducing genetic material from Mars to Earth seems insignificant

This is the stuff of science fiction. Yet similarly conjectural risks had to be considered in the development of atomic energy, production of antibiotics and the use of live virus vaccines

Arie Zuckerman is Professor and Head of this Department of Medical Microbiology and the WHO Collaborating Centre for Reference and Research on Viral Hepatitis at the London School of Hygiene and Tropical Medicine.

climatology supplement

The World Climate Programme

B. J. Mason

In recent years there has been an upsurge of interest in climate and its variations, the prediction of future trends and their consequences. Increasing world population and higher living standards have increased the pressure on natural resources of food, fibre, energy and water, the balance between the supply and demand for which could be seriously affected by even temporary changes in the climate of critical regions. The impact of any such changes will depend not only on their magnitude but also on the speed with which they occur. There is also increasing concern that man himself may induce inadvertent changes of climate by polluting the atmosphere with increasing quantities of carbon dioxide, heat, aerosols and chemicals. Although there has been a tendency to exaggerate the magnitude and consequences of the climatic fluctuations likely to occur in the next 100 years, future changes are likely to have greater economic and social impact than those of the past. The whole subject of climate, its variations and consequences therefore merits thorough and critical investigation.

In response, the World Meteorological Organization and the International Council of Scientific Unions, in collaboration with other international agencies, are planning a World Climate Programme spanning the two decades 1980–2000, preceded by a World Climate Conference in Geneva in February 1979 at which present knowledge will be reviewed and future plans discussed. The main objectives of the World Climate Programme may be summarised as follows: to improve knowledge of the natural variability of climate; to understand the underlying causes and mechanisms; to assess the sensitivity of climate to natural and man-made perturbations; and ultimately to predict future climatic changes; and to assist in the making of planning and investment decisions in climate-sensitive industries with a view to reducing the impact of adverse climatic changes. The Programme will have three main elements: a climate data and applications programme; a programme to investigate the impacts of climate on human activities; a programme for research on climatic change and variability.

Data and services

Although prediction of the magnitude and timing of climatic fluctuations is not yet possible, estimates of future probabilities can be made from analysis of past records of the main climatic parameters and these can serve as a useful input into the long-term planning of climate-sensitive industries such as agriculture, energy, water resources, transport and building and construction. A great deal of the available worldwide data are held in national meteorological services such as the British Meteorological Office where it is readily accessed by computer and used to answer some 30,000 enquiries each year from a wide spectrum of public services and industries. However, climatological observations need to be improved in many parts of the world where modern methods of data processing, analysis and presentation are required for the effective application of present knowledge to practical problems.

Impact studies

Very few studies have been made of the likely impact of marked and persistent changes in climate even on the major food-producing areas of the world. This would involve detailed analysis of relationships between weather and the growth and yield of the more important crops in different climatic environments. Such studies might pave the way for the forecasting of crop yields, on a regional or national basis, if and when reliable seasonal and longer term weather/climate forecasts become available.

Although it seems generally agreed that the greatest man-made potential threat to climate is the release of carbon dioxide by the burning of fossil fuels, no detailed and critical assessment of the likely effects has been made. It is not obvious that the overall result would be as detrimental as is usually assumed; it could even be beneficial. Although an average global warming of 5 °C with up to 10 °C in polar regions might well lead to substantial melting of the ice cap and widespread flooding, a more modest and more likely rise of 2–3 °C might well lead to increased food production by prolonging the growing seasons, increasing the rainfall and enhancing photosynthesis, and, furthermore, produce considerable savings in energy consumption. There will, no doubt, be some off-setting disadvantages but these should be assessed before assuming catastrophe.

Research

Study of past climates The reconstruction and study of past climates is necessary to determine the nature and extent of climatic fluctuations, to provide a guide to future changes and to validate computer simulations of past climates. Beyond the period of instrumental records the evidence rests strongly on modern techniques of radiocarbon dating and stable isotope analysis of fossils, ice cores, tree rings, and so on, which have greatly improved in recent years. These historical records, being dominated by irregular fluctuations, cannot be safely extrapolated to predict future changes. They can, however, be used to estimate the probability that fluctuations of a given magnitude, range and duration may occur within a given time interval and also to estimate the associated degrees of risk.

Climate monitoring Comprehensive data sets on the present climate are required to study mean annual and seasonal climates, for model development and validation, and to provide better climatological services. The First GARP Global Experiment (1978–79) will provide the first comprehensive set of weather observations covering one annual cycle. It will also be necessary to monitor at least the upper layers of the ocean, the ice sheets, changes in the land surface and its biological cover,

0028-0836/78/0276—0327$01.00

the incoming solar radiation, and the carbon dioxide, ozone and dust content of the atmosphere. Most of these data, except subsurface ocean data, should be provided by satellites within the next few years but their processing and archiving will require considerable additional effort.

As it may not be possible to understand, much less predict, long-term climatic changes without treating the atmosphere, oceans, ice sheets, land surface and biosphere, as a single interactive system, the lack of oceanographic data may ultimately prove a serious obstacle. Although limited area and duration experiments, such as JASIN just concluded in the North Atlantic this summer, will help to elucidate interactions between the upper layers of the ocean and the atmosphere, long-term climatic changes may be induced by changes in the deep ocean circulation. These will be difficult to monitor on a fully global basis but carefully planned measurements in critical areas should provide important clues and will probably form part of the World Climate Programme to be implemented over several years as a concerted international effort.

Computer modelling Although the processes involved in the maintenance of the Earth's present climate are broadly known, those responsible for climatic fluctuations are largely unknown. Predictions of the extent and duration of climatic changes are not possible at present and must await greater knowledge and understanding of the underlying causes, whether internal or external to the atmosphere. As the climatic system embraces the atmosphere, hydrosphere, cryosphere, lithosphere and biosphere and a great variety of processes and interactions over a wide spectrum of space and time scales, their synthesis requires the building of very complex computer models of the type described in this supplement by A. Gilchrist. However, the construction, testing and evaluation of such models is a major undertaking requiring scientific resources and great computing power that is presently available only in the USA and at the British Meteorological Office where remarkable progress has been made in simulating the main features of the present global climate including seasonal changes and important regional features such as the monsoons. The models may also be used with some confidence to investigate the response of climate to conceivable natural and man-made perturbations. For example, the British Meteorological Office (Mason, B. J. *Proc. R. Soc.*, **A,** in press) has carried out a wide range of model experiments to assess the likely effects of changes in solar radiation, soil moisture and vegetation cover, sea-surface temperatures, polar ice cover, and so on, and of conceivable man-made changes in the carbon dioxide, ozone, dust and heat content of the atmosphere, and to judge whether these are likely to be distinguishable from natural climatic fluctuations. Also, by testing the sensitivity of the statistics generated by the model to variations in a particular parameter or combination of parameters, one may hope to discover the underlying causes of climatic change. However, it is sometimes difficult to assess the significance and reliability of a particular result especially if the analysis of the experiment has not clearly revealed the response mechanism of the model and there have been insufficient tests to assess the significance of the signal relative to the noise generated by the model. The response (signal) to a prescribed perturbation will be statistically significant only if the difference in the mean values of the perturbed and standard (control) states can be discriminated from the model noise as estimated, for example, by its time-averaged response to random perturbations in the initial conditions. There is a general impression that the models exhibit less variance than the real atmosphere; if this is so, it may be easier to detect a perturbation signal above the noise in a model than in the real atmosphere. It therefore seems important to compare not only mean values but the models' simulated variance with observations. All this implies a long, arduous programme of model development, improvement and assessment with the object of narrowing the degree of uncertainty in the answers they provide.

Prediction The prediction of future climatic changes, as distinct from the simulation and sensitivity studies just mentioned, poses a formidable scientific problem partly because it is not possible to verify such long-term predictions against observation. Prediction of climatic variations induced by changes in external forcing factors such as the incoming solar radiation, changes at the boundaries of the climatic system, or by man's activities presupposes that these stimuli can be predicted accurately in advance. Aside from this the precision of any climatic prediction, expressed as a set of climatological statistics, will be limited by random or spontaneous internal fluctuations within the real climatic system and by the extent to which these are reproduced by the model. When integrated over long periods with fixed boundary and external conditions models are likely to approach an equilibrium state and produce climate statistics largely independent of the transient features of the initial state.

There is, however, the possibility that the real climatic system, being highly non-linear, may be able to exist in two or more quasi-stable modes and change rather abruptly from one such state to another. The transitions between glacial and interglacial epochs are suggestive of such changes. If such transitions are externally induced, they are probably predictable, at least in principle. If, however, they can arise spontaneously from internal reconfiguration of the climatic system they may not be predictable by models that are damped sufficiently to ensure dynamical and computational stability. In any case, soundly based long-range climatic predictions are not likely to be possible within the next decade.

I hope that this introduction may give some indication of the scope, complexity and difficulty of the climatic problem, illustrate the need for substantial and sustained programmes at both national and international level, and engender a more sceptical attitude towards the ill-founded and often alarmist statements that bedevil this subject. ☐

B. J. Mason is Director-General of the Meteorological Office, Bracknell, UK.

Historical climatology

M. J. Ingram, D. J. Underhill & T. M. L. Wigley

Climatic Research Unit, School of Environmental Sciences, University of East Anglia, Norwich, UK

Descriptive documentary evidence is an important source of detailed information on past climates, particularly for the period between the eleventh century and the beginning of the era of instrumental meteorology. Historical climatology is concerned with the study and climatic interpretation of this evidence. However, there are many pitfalls in using historical records, associated with the fact that such records were rarely written primarily as descriptions of climate and with the fact that many readily accessible records are of doubtful reliability. Here we take a critical look at existing work in the field, with the aim of isolating many problems which need to be recognised and overcome before historical climatology can be considered to rest on a secure methodological and factual footing.
